# About the Editors

---

## Volume 1

### Editor-in-Chief

**Frederick T. L. Leong, Ph.D.**, is Professor of Psychology (Industrial/Organizational and Clinical Psychology Programs) and Director of the Center for Multicultural Psychology Research at Michigan State University. He has authored or co-authored more than 110 arti-

cles in various psychology journals, as well as 70 book chapters. In addition, he has edited or co-edited 10 books. Dr. Leong is a Fellow of the APA (Divisions 1, 2, 12, 17, 45, 52), Association for Psychological Science, Asian American Psychological Association, and the International Academy for Intercultural Research. His major research interests center around culture and mental health, cross-cultural psychotherapy (especially with Asians and Asian Americans), and cultural and personality factors related to career choice and work adjustment. He is past president of APA's Division 45 (Society for the Psychological Study of Ethnic Minority Issues), the Asian American Psychological Association, and the Division of Counseling Psychology in the International Association of Applied Psychologists. He is currently serving on the APA Board of Scientific Affairs, the Minority Fellowship Program Advisory Committee, and the Commission on Ethnic Minority Recruitment, Retention, and Training (CEMRRAT2) Task Force. He is the 2007 co-recipient

of the APA Award for Distinguished Contributions to the International Advancement of Psychology.

### Senior Editor

**Elizabeth M. Altmaier, Ph.D.**, is Professor of Counseling Psychology in the College of Education and a Professor of Community and Behavioral Health in the College of Public Health, University of Iowa. She received her master's in psychology and her doctorate in Counseling Psychology from Ohio State University. Her bachelor's in

psychology was from Wheaton College, Illinois. She has an extensive record of research in health applications of counseling psychology, focusing primarily on the role of coping resources (e.g., optimism, coping responses, spirituality/religiosity) in long-term adjustment after treatment for cancer and chronic pain. Altmaier has been involved in professional issues in the psychology community, serving on such boards/committees as the Committee on Accreditation and the Joint Designation Committee of ASPPB/National Register. She is currently associate editor of *The Counseling Psychologist*; she previously was associate editor of the *Journal of Counseling Psychology* and editor of *Clinician's Research Digest*.

### Associate Editor

**Brian D. Johnson, Ph.D.**, is Professor in the School of Applied Psychology and Counselor Education at the University of Northern Colorado in Greeley, CO. He is also the coordinator and director of training for his university's APA accredited Counseling Psychology

Program. Johnson received his doctorate in Counseling Psychology at the University of Iowa. His scholarship focuses on the assessment and treatment of childhood disorders, parenting and health psychology. He has served as a reviewer for the *Journal of Counseling Psychology*, *The Counseling Psychologist* and the *Journal of Clinical Child and Adolescent Psychology*. He is a licensed psychologist in the state of Colorado.

### Editor-in-Chief

**Frederick T. L. Leong, Ph.D.**, is Professor of Psychology (Industrial/Organizational and Clinical Psychology Programs) and Director of the Center for Multicultural Psychology Research at Michigan State University. He has authored or co-authored more than 110 arti-

cles in various psychology journals, as well as 70 book chapters. In addition, he has edited or co-edited 10 books. Dr. Leong is a Fellow of the APA (Divisions 1, 2, 12, 17, 45, 52), Association for Psychological Science, Asian American Psychological Association, and the International Academy for Intercultural Research. His major research interests center around culture and mental health, cross-cultural psychotherapy (especially with Asians and Asian Americans), and cultural and personality factors related to career choice and work adjustment. He is past president of APA's Division 45 (Society for the Psychological Study of Ethnic Minority Issues), the Asian American Psychological Association, and the Division of Counseling Psychology in the International Association of Applied Psychologists. He is currently serving on the APA Board of Scientific Affairs, the Minority Fellowship Program Advisory Committee, and the Commission on Ethnic Minority Recruitment, Retention, and Training (CEMRRAT2) Task Force. He is the 2007 co-recipient of the APA Award for Distinguished Contributions to the International Advancement of Psychology.

### Senior Editor

**Howard E. A. Tinsley, Ph.D.**, is Professor Emeritus of Psychology at Southern Illinois University at Carbondale, a professor in the WLRA International Centre of Excellence at Wageningen University in the Netherlands, and a member of the Mukilteo, Washington,

City Council. He has taught at the University of Oregon, University of Florida, and Southern Illinois University at Carbondale (where he was director, graduate training program in counseling psychology) and he has held appointments as a visiting scholar at the University of Texas at Austin, the University of Minnesota–Twin Cities, and the University of Washington. He received his Ph.D. in psychology from the University of Minnesota and was a licensed psychologist in Illinois (now inactive) and a Diplomate of the American Board of Vocational Experts (now inactive). Tinsley has served as the Editor of the *Journal of Vocational Behavior* and *Passages*, Guest Editor of the *Journal of Counseling Psychology* and *Leisure Sciences*, Advisory Editor of *Contemporary Psychology*, Associate Editor of the *Encyclopedia of Career Decisions and Work Issues*, and Associate and Book Review Editor of the *Journal of Leisure Research*. He has served on the Editorial Boards of nine prominent psychology journals and the Editorial Advisory Board of the Test Corporation of America, and reviewed manuscripts for 26 psychology research journals. He is the lead editor of the

*Handbook of Applied Multivariate Statistics and Mathematical Modeling*, author of 19 book chapters and more than 150 publications dealing with leisure, vocational psychology, and psychological measurement. Tinsley is a recipient of the research award of the American Rehabilitation Counseling Association and the Allen V. Sabora Research Award for research excellence in leisure psychology. A Fellow of the American Psychological Association, Western Psychological Association, and American Psychological Society, he is a former Chair of the American College Personnel Association Commission on Assessment, a former member of the Board of the Council of Counseling Psychology Training Programs, and a former President and secretary-treasurer of the Academy of Leisure Sciences.

### Associate Editor

**Suzanne H. Lease, Ph.D.**, is Associate Professor and Training Director of Counseling Psychology in the Department of Counseling, Educational Psychology, and Research at the University of

Memphis. She also taught at Luther College in Decorah, Iowa. She received her Ph.D. in Psychology (Counseling) from Southern Illinois University at Carbondale and is a licensed psychologist (Health Service Provider) in the state of Tennessee. Her teaching interests include Theories of Counseling, Vocational Psychology, Multicultural Counseling, and Practicum supervision. Her research topics address career development; multiculturalism; masculinity; and gay, lesbian, and bisexual (GLB) issues. Current manuscripts focus on cross-cultural and cross-racial understandings of masculinity in work and intimate partner relationships and family influences on career development. She received the 2006 Dean's Excellence in Research and Scholarship award from the College of Education, University of Memphis. She serves on the Editorial Board for the *Journal of Counseling Psychology* and is an ad-hoc reviewer for several other journals.

## Volume 3

### Editor-in-Chief

**Frederick T. L. Leong, Ph.D.**, is Professor of Psychology (Industrial/Organizational and Clinical Psychology Programs) and Director of the Center for Multicultural Psychology Research at Michigan State University. He has authored or co-authored more than 110 articles in

various psychology journals, as well as 70 book chapters. In addition, he has edited or co-edited 10 books. Dr. Leong is a Fellow of the APA (Divisions 1, 2, 12, 17, 45, 52), Association for Psychological Science, Asian American Psychological Association, and the International Academy for Intercultural Research. His major research interests center around culture and mental health, cross-cultural psychotherapy (especially with Asians and Asian Americans), and cultural and personality factors related to career choice and work adjustment. He is past president of APA's Division 45 (Society for the Psychological Study of Ethnic Minority Issues), the Asian American Psychological Association, and the Division of Counseling Psychology in the International Association of Applied Psychologists. He is currently serving on the APA Board of Scientific Affairs, the Minority Fellowship Program Advisory Committee, and the Commission on Ethnic Minority Recruitment, Retention, and Training (CEMRRAT2) Task Force. He is the 2007 co-recipient of the APA Award for

Distinguished Contributions to the International Advancement of Psychology.

### Senior Editor

**Madonna G. Constantine, Ph.D.**, is Professor of Psychology and Education in the Department of Counseling and Clinical Psychology at Teachers College, Columbia University. She received her doctorate in Counseling Psychology from the University of Memphis and completed bachelor's and master's degrees from Xavier University of New Orleans.

Constantine is a highly esteemed researcher in the areas of Black psychology and multicultural counseling. The scope of her work includes exploring the psychological, educational, and vocational issues of African Americans; developing models of cross-cultural competence in counseling, training, and supervision; and examining the intersections of variables such as race and ethnicity in relation to mental health and educational processes and outcomes. Constantine is currently serving as associate editor for the *Journal of Counseling Psychology* and *Cultural Diversity & Ethnic Minority Psychology*. She also is involved in various leadership capacities in counseling and psychological associations across the country.

## Associate Editor

**Roger L. Worthington, Ph.D.**, currently serves as Interim Chief Diversity Officer at the University of Missouri–Columbia (MU), where he directs the Chancellor’s Diversity Initiative. He is a member of the Board of Directors of the National Association of Diversity Officers in Higher Education (NADOHE) and

serves on the editorial board of the *Journal of Diversity in Higher Education*. In the past he has also served on the editorial boards of the *Journal of Counseling Psychology* and *The Counseling Psychologist*. Worthington has an extensive record of scholarship, including theoretical and empirical articles and book chapters related to race/ethnicity, gender, sexual orientation identity, social class, and religious expression.

He has been a principal investigator or co-investigator on nearly \$500,000 in internal and external grants. He is the principal investigator and project director of the MU Difficult Dialogues Program, a project funded by a prestigious Ford Foundation grant. The focus of the MU Difficult Dialogues Program is to promote greater understanding of the relationships among academic freedom, academic responsibility, and intellectual pluralism in a climate characterized by divisiveness and mistrust among those holding differing cultural, religious, and political viewpoints. In addition to his role directing the Chancellor’s Diversity Initiative, he is a licensed psychologist (MO) and an associate professor of Educational, School, and Counseling Psychology at MU, where he has taught courses to undergraduate and graduate students on counseling skills, ethics and law for professional psychology, research design, measurement, and human diversity.

### Editor-in-Chief

**Frederick T. L. Leong, Ph.D.**, is Professor of Psychology (Industrial/Organizational and Clinical Psychology Programs) and Director of the Center for Multicultural Psychology Research at Michigan State University. He has authored or coauthored more than 110 arti-

cles in various psychology journals, as well as 70 book chapters. In addition, he has edited or co-edited 10 books. Dr. Leong is a Fellow of the APA (Divisions 1, 2, 12, 17, 45, 52), Association for Psychological Science, Asian American Psychological Association, and the International Academy for Intercultural Research. His major research interests center around culture and mental health, cross-cultural psychotherapy (especially with Asians and Asian Americans), and cultural and personality factors related to career choice and work adjustment. He is past president of APA's Division 45 (Society for the Psychological Study of Ethnic Minority Issues), the Asian American Psychological Association, and the Division of Counseling Psychology in the International Association of Applied Psychologists. He is currently serving on the APA Board of Scientific Affairs, the Minority Fellowship Program Advisory Committee, and the Commission on Ethnic Minority Recruitment, Retention, and Training (CEMRRT2) Task Force. He is the 2007 co-recipient of the APA Award for Distinguished Contributions to the International Advancement of Psychology.

### Senior Editor

**W. Bruce Walsh, Ph.D.** (University of Iowa), is Professor Emeritus in the Department of Psychology at Ohio State University and currently involved in consulting activities. Walsh is the founder and charter

editor of the *Journal of Career Assessment* and the *Biennial Review of Counseling Psychology*. He has coauthored and coedited 24 books, including *Tests and Assessment*, *Tests and Measurements*, *Career Counseling*, *Career Counseling for Women*, *Career Counseling for African Americans*, the *Handbook of Vocational Psychology*, the *Handbook of Career Counseling*, *Counseling Psychology and Optimal Human Functioning*, and *Person-Environment Psychology*. Walsh currently serves on the editorial boards of the *Journal of Vocational Behavior* and the *Career Development Quarterly*. In 1998 he served as President of the Society of Counseling Psychology (Division 17) and from 2001–2007 served as the APA Council Representative for Division 34 (Population and Environment). From 1990 to 2002 he served as the Director of Training for the Counseling Psychology Program at Ohio State. In 2004 he received the Leona Tyler Award from the Society of Counseling Psychology in recognition of outstanding accomplishments. He holds Fellow status in the American Psychological Association and the Association of Psychological Science and is licensed as a psychologist in Ohio.

### Associate Editor

**Paul J. Hartung, Ph.D.**, is Professor of Behavioral Sciences at Northeastern Ohio Universities Colleges of Medicine and Pharmacy, and Adjunct Professor of Counseling at the University of Akron. His scholarship focuses on developmental

career theory and practice, work–life integration, career decision making, medical career development, and communication in medicine. Hartung serves on the editorial boards of *Journal of Vocational Behavior*, *Journal of Career Assessment*, *Career Development Quarterly*, and *Journal of Counseling and Development*. He is a licensed professional counselor in the state of Ohio and a National Certified Counselor.

# Introduction

---

## The Field

Counseling is a professional activity that involves helping clients, individually or in groups, or as couples and families, deal with various career, vocational, educational, and emotional problems. From the depressed and lonely college student to the business executive at midlife experiencing decreasing levels of career satisfaction to the couple where one partner has been unfaithful in the relationship, counseling is the intervention that numerous individuals turn to each year as the challenges and stress of daily living exceed their normal coping abilities. Counseling is practiced by counselors, social workers, psychiatric nurses, psychologists, and psychiatrists. While the demarcation is not absolute, counseling is sometimes differentiated from psychotherapy in that the latter deals more with mental illnesses and psychological disorders while the former is more concerned with normative stresses, adjustment difficulties, and life transitions (e.g., adjusting to unemployment or going through a divorce). Yet others have maintained that counseling and psychotherapy are quite similar activities and represent different sides of the same coin. In the current encyclopedia, we have adopted this latter perspective and counseling and psychotherapy are used interchangeably depending on the problem being treated as well as the context of the intervention.

Within the United States, traditionally, there have been four recognized mental health professions, which include Psychiatry, Psychology, Social Work, and Nursing in terms of insurance reimbursement of mental health services. Counseling can be provided to their clients by each of these mental health professionals. Within the field of Psychology, there are four major applied specialties in professional psychology which include Counseling Psychology, Clinical Psychology, School Psychology, and Industrial/Organizational

Psychology. Counseling, Clinical, and School Psychology are considered health service specialties while Industrial/Organizational Psychology is not. There is considerable overlap in the training and practice of Clinical and Counseling Psychology, and a few clinical and counseling training programs are housed within the same university department.

Both Clinical Psychology and Counseling Psychology can be differentiated from Psychiatry by the fact that the latter professionals are first trained to be physicians (receiving a medical degree) who go on to obtain specialty training (psychiatric residencies and fellowships) and can prescribe medications. Until recently, psychologists could not prescribe medications while psychiatrists could. This difference has changed considerably with the movement towards gaining prescription privileges for psychologists with special post-doctoral training. Another important distinction between psychiatrists and psychologists is that the majority of the former group tends to have admitting privileges in hospitals for their patients while the latter group does not, important for mental health professionals treating patients with severe mental illnesses who often require hospitalization.

As an applied specialty in Psychology that focuses on health and mental health, Counseling Psychology uses an extensive array of assessment and intervention strategies to help individuals, families, groups and organizations with their educational, developmental, and adjustment difficulties. While a small subset of counseling psychologists do focus on health issues, the majority of them focus instead on mental health in either their research or practice. The breadth of the activities undertaken by counseling psychologists has often resulted in their being referred to as the “general practitioners” of psychological specialties.

With a long-standing tradition of focusing more on clients’ strengths and assets as opposed to their

deficits and pathology, counseling psychologists are different from clinical psychologists along four main inter-related dimensions: (a) they tend to provide interventions and treatment for persons who are experiencing adjustment difficulties and moderate levels of psychological problems as opposed to severe psychopathology, (b) they are more likely to use short-term interventions, (c) they tend to provide these interventions in outpatient as opposed to inpatient facilities, and (d) they are unique among applied psychologists in providing individual career counseling and educational interventions. However, in providing individual counseling and psychotherapy, they are quite similar to clinical psychologists in using some of the same theories, models, and approaches.

The Social Work degree is primarily a practitioner degree with limited training in conducting science. As a mental health profession, most social workers complete the MSW (Master's of Social Work) which is a two-year master's degree. Most social workers eventually seek certification, to provide mental health services in private practice or various mental health agencies. Like clinical and counseling psychologists, social workers can provide therapy to clients with mental health problems, and similar to a majority of their psychology colleagues, social workers also cannot prescribe medicines for mental health problems. Social workers and psychiatrists can also be distinguished from counseling psychologists by the fact that they do not receive any training in psychological testing and assessment. In psychiatric hospitals, VA's, and community mental health centers, clinical and counseling psychologists are charged with engaging in the bulk of the psychological testing and test report preparation.

Within Nursing, only those who are trained as psychiatric nurses are considered mental health professionals and can engage in private practice of counseling and psychotherapy. Even though psychiatric nurses can engage in such private practice, the majority of them tend to work in mental health hospitals or agencies. As a health profession, psychiatric nursing is closely aligned with the medical specialty of psychiatry and is an integral member of the interdisciplinary mental health team in most psychiatric hospitals. As such, they are more likely to be found in inpatient than outpatient mental health facilities, though nurse-practitioners (those who can prescribe certain psychotropic medications) are becoming more common in some mental health agencies to alleviate the workload burden on psychiatrists. Like social workers,

they do not obtain any training in scientific research or psychological testing when contrasted with counseling or clinical psychologists.

A fifth profession, which is closely aligned with Counseling Psychology and often confused with it, is that of the Counseling field. Unlike counseling psychologists who are trained primarily as psychologists, masters and doctoral degree counselors receive training in counseling programs that are not accredited by the American Psychological Association and therefore cannot be licensed as psychologists. Instead, counselors are trained in counseling programs typically accredited by the Council on Counseling and Related Educational Programs (CACREP). These counselors typically go on to achieve state licensure as professional counselors. While the training between the two groups is quite similar, a majority of the counselors are trained at the masters level whereas counseling psychologists are required to have a doctorate in order to be licensed and to practice independently. While some are active in both, counseling psychologists tend to belong to and participate in the American Psychological Association whereas counselors tend to belong to and participate in the American Counseling Association.

### **Rationale for the Encyclopedia**

When Nancy Hale from Sage approached me about editing the encyclopedia back in 2002, I hesitated since I knew that editing an encyclopedia would be very time consuming and would take away from my program of research and other professional activities. Yet, I accepted the invitation because of two of my strongest beliefs regarding psychology. First, I had learned and remembered in graduate school Kurt Lewin's famous dictum: "There is nothing so practical as a good theory." Second, as I became involved in the American Psychological Association, I learned about this wonderful idea from George Miller in his 1969 Presidential address about "Giving Psychology Away." The idea that Psychology should not be locked in academic journals and research labs but given away freely to the public so that we could fulfill the APA mission of "promoting human welfare" made a great deal of sense to me. Therefore, the primary rationale for this encyclopedia is the combination of those two powerful ideas of "giving psychology away" and sharing "practical theories" with the public.

Whether performed by psychologists, psychiatrists, social workers, psychiatric nurses or counselors, thousands of professionals throughout this country and elsewhere in the world are providing counseling services to their fellow human beings in helping them address and resolve the variety of problems of living that exceeds their coping resources and social support. The purpose of the current *Encyclopedia of Counseling* is to provide a comprehensive overview of the theories, models, techniques and challenges involved in this professional activity called counseling. It was designed to be the definitive resource for members of the public who are interested in learning about the science and practice of counseling. It will also be a useful resource for undergraduate and graduate students as well as professionals from other specialties to learn about counseling in all its forms and manifestations.

## Content and Organization

By covering all of the major theories, approaches, and contemporary issues in counseling, the encyclopedia includes close to 600 entries. To enable the reader to understand the major approaches and themes within the field of counseling, the current encyclopedia has been divided into four volumes: (1) changes and challenges facing counseling, (2) personal and emotional counseling, (3) cross-cultural counseling, and (4) career counseling. However, each volume will also contain a cross-volume Reader's Guide and a cross-referencing system to entries in other volumes. In this way, we have created a flexible encyclopedia that can be used together as a set or separately by volume depending on the need of the user.

### ***Volume 1: Changes and Challenges for Counseling in the 21st Century*** **(Elizabeth Altmaier, Senior Editor;** **Brian Johnson, Associate Editor)**

In the first volume of the encyclopedia, we provide counselors, psychologists, scientists and students with a broad overview of contemporary applications in the field of counseling. Professional counselors come from a variety of disciplines including medicine, psychology, religion, social work, and education. Understanding our varying perspectives will help us better define who we are. Consequently, we provide a review of different

types of counselors, their different professional identities and their different models of graduate education. We also review important historical developments that have shaped the evolution of the counseling profession into its current form. Throughout these discussions, we keep an eye on how these past events continue to influence the field today and into the future.

As we continue through the 21st century, counseling is undergoing tremendous change. Forces within and outside the profession are changing the way counselors practice, select treatments, conduct research, and conceptualize clients. Counselors are working in a wider range of environments and with more clients. They are encountering new technologies and ethical dilemmas that a decade ago would not have even been considered. Charles Gelso and Bruce Fretz have noted that, for any field to avoid stagnation, it must be in a state of flux. Counseling is definitely in a state of flux. This volume's contents reflect both past history and newer applications. Topics will be of interest to both the practitioner and the scientist. Some topics reflect generally accepted ideas/practices while others will be controversial. All of the entries define the topics being discussed and also show how these topics are impacting professional counselors today and in the future.

We also identified numerous topics related to the application of treatment approaches and therapeutic techniques within a counseling relationship. Also included in this volume are special applications in the areas of Health, Life Transitions, Assessment, Youth/Families and Innovative Treatment Approaches. All of these special applications describe treatments in terms of current practice and also in terms of best practice. Empirical support for these treatments, when available, will be reviewed.

Our intent for this volume is to provide a look back at influential theories, models, persons and trends as well as look forward to likely paradigm shifts in research, theory and practice.

### ***Volume 2: Personal and Emotional Counseling*** **(Howard E. A. Tinsley, Senior Editor;** **Suzanne Lease, Associate Editor)**

Volume 2 of the *Encyclopedia of Counseling* provides psychologists, counselors, scholars, behavioral scientists, students and the public with a comprehensive compilation of contemporary information about

established and emerging topics in mental health and personal and emotional counseling.

Mental health professionals who provide personal and emotional counseling possess expert knowledge of the social, cultural and biological differences among individuals and the factors that contribute to human diversity. They have a detailed understanding of the major theories and empirical research findings that illuminate the dynamic influence of biological, cognitive, social, cultural, and environmental forces on mental health and life-span development. They understand the principles of psychological measurement and are skilled in the use of assessment techniques to determine the nature of their clients' concerns. They are trained in the use of therapeutic interventions to ameliorate those concerns. They view those who seek their services as clients rather than patients and they interact with their clients as coaches, educators and mentors to promote client learning.

The problems addressed in personal and emotional counseling range from those arising from concerns about normal developmental processes and common life transitions to debilitating problems of great severity (e.g., depression, suicidal thoughts or personality disorders). The problem may be chronic or acute, and it may have a social, cultural, or biological etiology.

Personal and emotional counseling encompasses a broad array of interventions that are used to provide assistance to single individuals, families, and groups of individuals having similar concerns. Many interventions involve some form of "talking therapy" (typically referred to as psychotherapy, or therapy) designed to help the client gain insight into the nature and causes of their concerns. Other interventions involve some form of behavioral rehearsal, the prescription of medication (most often by a psychiatrist or general medical practitioner), or a combination of approaches.

Interventions may be designed to prevent future problems, develop needed skills, or correct problems (i.e., restore mental health and effective functioning; APA, 1999). The overarching goals of personal and emotional counseling are to help the client make a choice (i.e., make a decision), change a troublesome behavior, or reduce cognitive confusion. Achieving these goals may necessitate acquiring new knowledge, modifying beliefs and values, learning new behaviors, understanding and adjusting to changing life circumstances, learning new emotional reactions, developing new interests, or resolving a crisis. Counseling helps clients view their concerns from a

new perspective, explore their options, and make decisions that bring about change.

Volume Two covers issues related to: (a) the healthy personality, (b) factors that affect mental health (cause difficulties), (c) assessment and diagnosis, (d) interventions, (e) outcomes of counseling and therapy.

**Volume 3: *Cross-Cultural Counseling* (Madonna Constantine, Senior Editor; Roger Worthington, Associate Editor)**

Volume 3 of the *Encyclopedia of Counseling* provides students, educators, practice professionals, and service consumers with a comprehensive overview of contemporary conceptual, scientific and applied topics in cross-cultural counseling. We acknowledge that human diversity is multifaceted with respect to dimensions of race, ethnicity, culture, language, gender expression, sexual orientation, ability and disability, religious and spiritual beliefs, and socioeconomic status, among others. Our charge for this volume is to focus narrowly on the topics of race, culture, and ethnicity, and allow the other dimensions of diversity to be infused throughout this volume and other volumes of the encyclopedia.

Cross-cultural counseling and psychotherapy have become highly influential in practice, training, and scholarship. Following decades of efforts to respond to social, political and demographic forces, multiculturalism has been identified as the fourth force in psychology. Demographic changes in the United States due to birthrates and immigration have increased the rapidity of response from the counseling profession in addressing the needs of racial, ethnic, cultural, and linguistic minorities. Changes to the field have occurred in the recruitment and training of graduate students, an increased emphasis on addressing cross-cultural topics in the scholarly discourse, and an expansion of service delivery models to make counseling more accessible. The professions have become increasingly concerned with issues of advocacy, civil rights, and social justice in order to combat the impact of oppressions on the lives of individuals. As a result, counseling roles and activities have expanded beyond the consultation room and into communities, educational systems and governmental agencies.

In this volume, we address the major social, scientific, and professional forces that have shaped the evolution of cross-cultural counseling and psychotherapy.

Progress is charted via coverage of historical developments that occurred in professional associations, journals, books, conferences, as well as national and world events. We address the roots of the field, as well as major changes in its development across time to the present. We identify major scientific, conceptual and practical advances, as well as the major contributors and architects in the field. We highlight important concepts, and address the impact of cross-cultural counseling and psychotherapy to the counseling profession more broadly. Emerging issues and topics are also identified.

**Volume 4: Career Counseling**  
(**W. Bruce Walsh, Senior Editor;**  
**Paul Hartung, Associate Editor**)

This volume of the encyclopedia provides psychologists, counselors, academics, researchers, and students with complete and contemporary information about established and emerging topics in career counseling. We define career counseling as efforts to facilitate satisfying and realistic decision-making and career adjustment throughout the life span. The task of the career counselor is to facilitate the learning of skills, interests, beliefs, values, work habits, and personal qualities that enable each client to create a satisfying life within a constantly changing work environment (Krumboltz, 1996). Career counselors may be seen as coaches, educators, and mentors.

We have chosen to use Walsh's definition of career counseling which makes three important assumptions. First, all career counseling models assume that the exchanges between counselors and clients lead to a change in client's vocational behavior and attitudes. In theory, career counseling promotes career decision-making, choice, adjustment, and a better life. A second assumption is that all models of career counseling involve information gathering. Any information about individuals or their environments that contributes to understanding vocational behavior, attitudes, and emotions needs to be considered in the career assessment and counseling process. Self-report interview data, psychometric assessment data, behavioral data, perceptions of others, and any other relevant information need to be considered. A third assumption is that all career counseling models involve a learning process—cognitive, behavioral, and affective learning. The learning process leads to changes in career cognitions, career behavior, and career emotions. The task of career counseling is to promote client learning.

In structuring a framework for career counseling, Mark Savickas identified six different questions that career clients ask: (a) How do I get a job? (b) What shall I choose? (c) Who am I? (d) How do I shape my career? (e) How can work help me grow as a person? (f) How can I do better? Each of these questions calls for different kinds of career counseling interventions, often offered by different kinds of agencies. Well-trained career counselors are prepared to offer services to address each of these career-related questions.

### How the Encyclopedia Was Created

Nancy Hale from Sage contacted Frederick Leong about the possibility of editing an *Encyclopedia of Counseling* in the summer of 2002. Following on some preliminary e-mail exchanges, Nancy moved over to the Journals Division of Sage and Arthur Pomponio took over as the Acquisition Editor for the encyclopedia. After additional discussions between Leong and Pomponio, it was decided that given the breadth of the Counseling field, the encyclopedia would consist of 4 volumes and approximately 150 entries per volume. Leong also suggested the novel approach of organizing the encyclopedia so that each volume covered a specific area of Counseling while maintaining the alphabetical ordering of entries within each volume.

Since Leong had also served as Associate Editor for International and Cross-Cultural entries under the senior editorship of Anthony Marsella for the *APA/Oxford Encyclopedia of Psychology* (8 volumes, Alan Kazdin served as Editor-in-Chief), he suggested using a similar organizational structure for the *Encyclopedia of Counseling*. Specifically, Leong would serve as Editor-in-Chief with the assistance of a Senior Editor to oversee each volume. The Senior Editor would in turn appoint an Associate Editor to help with the volume. In addition, this editorial team of 9 individuals would be guided by an Advisory Board.

Once the focus of the encyclopedia and the organizational structure of the four volumes were in place, Leong submitted a formal proposal to Sage which sent it out for external review. Upon receiving positive review of the proposal, Rolf Janke, then-Executive Editor of Sage, met with Frederick Leong at the University of Tennessee in December 2003 to review and sign the contract to initiate the project. In consultation with Janke and Pomponio, Leong appointed some of the leading figures of the field to serve on the

Advisory Board. The Board consisted of individuals from a variety of groups within the Counseling field. Members of the Board include Patricia Arredondo (incoming President of the American Counseling Association at that time), Charles Gelso (former editor of the *Journal of Counseling Psychology* and eventually Editor of *Psychotherapy: Theory, Research, Practice and Training*), Punccky Heppner (incoming President of the Society for Counseling Psychology of the American Psychological Association at that time), Francis Lu (Professor of Psychiatry at University of California, San Francisco and leading authority on cross-cultural competence training in Psychiatry), Paula Nurius (Professor of Social Work at the University of Washington and an author of several books with Sage), and Derald Wing Sue (leading author and authority on cross-cultural counseling).

With the Advisory Board in place, the Senior Editors of the volumes were appointed next with Elizabeth Altmaier (University of Iowa) serving as Editor of Volume 1, Howard E. A. (Tony) Tinsley (Professor Emeritus, Southern Illinois University) serving as Editor of Volume 2. Madonna Constantine (Teachers College, Columbia University) was appointed as Editor of Volume 3 and W. Bruce Walsh (Professor Emeritus, Ohio State University) accepted the appointment to be Editor of Volume 4. Each of these Volume Editors then appointed their Associate Editors: Brian Johnson (Volume 1), Suzanne Lease (Volume 2), Roger Worthington (Volume 3), and Paul Hartung (Volume 4).

The next step involved generating the headword list of entries of the encyclopedia. Based on a review of the leading textbooks and handbooks in Counseling and Counseling Psychology, an initial list was generated by the Editor-in-Chief. This list was then sent to each of the Senior and Associate Editors for the 4 volumes for their review as to which entries fit best in their volume. As a result of this review, some entries were dropped and new ones were added. Based on this review and consultation across volumes, the penultimate list of entries for each volume was decided upon and then sent to the Advisory Board for their comment and suggestion. Using the feedback from the Board, another round of additions and deletions was conducted which resulted in the final list of entries. Next the challenge of recruiting the hundreds of contributors to write the entries began.

When the *Encyclopedia of Counseling* began in earnest in 2004 with the appointment of the editorial team and advisory board, Sage had just implemented their Web-based tool for their Reference Division, the Sage Reference Tracking (SRT) system. The SRT was to prove to be an invaluable tool for the editorial team since it allow the management of contracts, submissions, revisions and acceptance of entries via the Web. Just a few years before, Leong had had to manage the entries assigned to him for the *Encyclopedia of Psychology* (APA/Oxford University Press) via hard copies and the U.S. Postal Service!

As a massive undertaking (9 editors, 4 volumes, almost 600 entries and over 1 million words), the encyclopedia took 4 years to complete and was finally published in 2008.

It was truly a team effort harnessing the efficiency of the Internet and involving hundreds of scholars, researchers, practitioners and editorial staff at Sage.

## Acknowledgments

As indicated above, the major undertaking of producing a four-volume encyclopedia would not be possible without the host of dedicated individuals. It is only fitting to acknowledge here the important contributions of all these individuals. To begin with, the encyclopedia is the product of the hundreds of contributors who wrote the entries and our acknowledgements should appropriately start with them. The contributors were ably guided by the editorial team who provided numerous hours of consultation and editing of the entries (Elizabeth Altmaier, Howard E. A. Tinsley, Madonna Constantine, Bruce Walsh, Brian Johnson, Suzanne Lease, Roger Worthington, and Paul Hartung). Both the editorial team and I owe much to the Advisory Board who provided important input into both the structure of the encyclopedia as well as the selection of the entries (Patricia Arredondo, Charles Gelso, Punccky Heppner, Francis Lu, Paula Nurius, and Derald Wing Sue).

Within Sage, there were many individuals who were pivotal in the launching of the encyclopedia (Nancy Hale, Arthur Pomponio, Kassie Graves, Rolf Janke) and seeing it through to production (Eileen Gallaher, Sara Tauber, and Carole Maurer), and we are grateful for their contributions as well as the scores of individuals in production, contracts, copyediting, typesetting, and cover design. Please know that we could not have done it without you. Thank you.

I have also been fortunate to have good colleagues and support within the Psychology Department at Michigan State University to carry out this project. While at the University of Tennessee, I was very ably assisted by my secretary Kim Kirby as well as talented graduate students (Annie Gupta, Huaiyu Zhang, Dwight Tolliver) and helpful colleagues (John Lounsbury and Mike Nash).

Finally, I would like to thank my wife, Sandy, and my daughters, Kate and Emily, who supported me throughout this project and only occasionally asked, "It's Saturday, why are you going to the office?" I also want to thank my Mom and Dad who instilled in me the work ethic to see projects to completion.

## ACCREDITATION BY THE AMERICAN PSYCHOLOGICAL ASSOCIATION

---

Counseling psychology training programs in the United States, Canada, and Puerto Rico may be accredited by the American Psychological Association (APA) and, if they are, must indicate so in their published materials. APA accreditation is a designation that publicly indicates that the accredited program, through a voluntary self-study and an external review, meets certain expected standards of quality and engages in ongoing evaluation and enhancement. The process of accreditation protects the interests of counseling psychology students and the general public through improving the quality of teaching, learning, research, and professional practice. Only graduate programs in professional psychology (counseling, clinical, or school psychology) at the doctoral level are accredited by the APA, not master's or specialist's level programs. Doctoral programs in counselor education are also not accredited by the APA; they may instead be accredited by the Council for Accreditation of Counseling and Related Educational Programs (CACREP). The APA, which has given the responsibility for accreditation of professional psychology programs to its Committee on Accreditation (CoA), also accredits professional psychology internship programs and postdoctoral residencies in professional psychology. The CoA carries out accreditation responsibilities consistent with the recognition provisions of the Council for Higher Education Accreditation (CHEA), which provides a list of accredited institutions and

programs to the U.S. Secretary of Education, who publishes it annually.

### Structure of the Accreditation Process

#### ***Committee on Accreditation***

In 1991, the APA outlined the foundation of a committee that would oversee the accreditation process in the *Policies for Accreditation Governance*. The committee members must represent a balance among graduate educators, practicing clinicians, and well-informed community citizens. Such a balance gives the committee the ability to scrutinize concerns from each of the three populations, thus creating a comprehensive accreditation process. The policy says that the CoA must consist of no fewer than 21 committee members. Four members must be graduate educators from psychology departments, ten members represent professional schools and training programs, four members are practicing professionals, two members are from the general public, and one member is a representative of graduate students. Of the ten members from professional schools and training programs, two each must be solicited by the Council of University Directors of Clinical Psychology, Council of Counseling Psychology Training Programs, Council of Directors of School Psychology Programs, National Council of Schools of Professional Psychology, and Association of Psychology Postdoctoral and Internship Centers.

The purpose of the CoA is to oversee formulation and implementation of accreditation policies and

procedures, render final accreditation decisions on education and training, evaluate accreditation policies and procedures, provide guidance and information regarding accreditation, establish guidelines for site visitors (see below), establish developmental and evaluative research on the accreditation process, establish task forces and review panels, and implement other responsibilities. The CoA proposes changes in policy after allowing for a period for public comment, finalizes the proposed changes, and sends them to the APA Board of Directors to adopt. A recent change was to the operating procedures of the CoA; these went into effect in 2005.

### ***Site Visitors***

Site visitors serve as representatives of the CoA in reviewing the quality and specific functions of the professional psychology program in question. They are professional clinical, counseling, and school psychologists or generalists who are psychologists in nonprofessional or nonpractice psychology disciplines. Site visitors who are professional psychologists must have earned a doctoral degree and have 5 years of experience working in a psychology field, hold an appropriate license or certification, and be active members of professional research organizations. Depending on the domain in which the professional psychologist works, he or she must also be associated with a doctoral training program, must have some association with a doctoral training program, or must be deemed to have adequate knowledge about educational, professional, and scientific issues in psychology. Site visitors who are generalists must have received a doctoral degree from a regionally accredited institution, have at least some professional experience, have some type of involvement with an institution that has an accredited training program, and be deemed to have adequate knowledge about educational, professional, and scientific issues in psychology. Site visitors must all be trained to be a site visitor or a site visit chairperson. They are evaluated postvisit by the program's training director and other site visitors. Although expenses are reimbursed by APA, neither members of the CoA nor site visitors receive any monetary compensation; they do this as an important professional service.

Site visitors represent the CoA but are not decision makers. They look at the training program based on the program materials and their actual visit. Materials include the self-study report that the program submits to the CoA and any material the CoA requests in

addition. During the visit, site visitors serve as the "eyes and ears" of the CoA. Site visitors observe the program and its quality in terms of the program's philosophy, goals, implementation of goals, and expected and documented outcomes. Site visitors review the training program based on the guidelines and policies in the *Guidelines and Principles for Accreditation of Programs in Professional Psychology*. After the visit and review of materials, the team writes a report to the CoA based on their observations. The program is given an opportunity to respond to the CoA about the site visit report. Based on the self-study, the site visit report, and the program's response to the site visit report, the CoA determines further action regarding accreditation status. The site team has no more contact with the program regarding the accreditation process.

### **Criteria of Accreditation**

The accreditation process was established to protect the rights of students, universities, consumers of psychological services, and community citizens. There are a number of requirements that need to be met before a program becomes accredited. The applicant program must provide evidence that it can and will ethically and effectively prepare students or trainees to provide psychological services to the public. The CoA recognizes that there are a variety of reliable and valid ways to effectively prepare students to serve the public. In reviewing the initial application of a program, the CoA will help the applying program formulate specific goals, encourage experimentation in achieving these goals, and suggest ways of constructing flexibility and reasonable freedom within these goals. Once the applicant program has set forth a model of training that has been approved by the CoA, site visitors will visit the program and review eight different domains in order for the CoA to determine whether the program should be accredited or not. The CoA and the site visitors will review the following: eligibility; program philosophy, objectives, and curriculum plan; program resources; cultural and individual differences and diversity; student-faculty relations; program self-assessment and quality enhancement; public disclosure; and relationships with accrediting body.

### ***Eligibility***

Site visitors assess whether the program is housed in an environment that is conducive to the appropriate

training of doctoral level students or trainees in professional psychology. To be eligible, the program needs to be sponsored by a regionally accredited higher education institution. The program also needs to have a mission statement congruent with the goals of the academic department in which it is housed; require each student to complete at least three years of academic coursework and one year of internship training before granting a doctoral degree; advocate for the development of students' understanding of cultural and individual diversity; and produce a viable means in which information regarding their program is shared with all interested parties.

### ***Program Philosophy, Objectives, and Curriculum Plan***

Site visitors look for evidence of congruence of the philosophy and plans of the program with the mission statement of the sponsoring institution, and they determine whether the institution is appropriate for training in the science and practice of professional psychology. The match between the program and the sponsoring institution is considered vital for students to receive an education that is comprehensive, complex, sequential, and cumulative. The team also reviews whether program training objectives prepare students to serve the general public. They review student records and materials such as syllabi, dissertations, and comprehensive examinations and conduct interviews with students, faculty, supervisors, administrators, and support staff to determine the consistency and quality of the program's philosophy and model of training, the substantive areas of professional psychology in which the students are trained, and the ability of the program to foster a high level of understanding of ethical, legal, and quality assurance issues related to the practice of psychology.

The site team also examines program curriculum to determine if all the major requirements are being met. The CoA expects that students have a comprehensive conceptualization of scientific psychology, theoretical foundations of psychology, diagnosis of difficulties through psychological assessment, cultural and individual diversity, and attitudes conducive to lifelong learning.

Last, site visitors assess whether each program has adequate and appropriate practicum experiences. Practicum sites should clearly commit to training, integrate practice with education, ensure that appropriate

experiences are consistent with the program's training model, and justify the sufficiency of the practicum experience in order for the student to be prepared for internship. Site visitors assess appropriate material and practices in internship and postdoctoral residency programs.

### ***Program Resources***

In regards to the program resources domain, the CoA is concerned with the ability of the program to successfully implement methods to achieve the stated mission, objectives, or goals. Site visitors assess whether or not the program has an identified core faculty (or supervisors) who are responsible for training, education, and supervision; has identified a sufficient number of quality students who have the necessary skills and abilities to effectively practice psychology; is housed in a stable learning environment; and effectively utilizes resources that enhance the level of preparation of the students or trainees.

### ***Cultural and Individual Differences and Diversity***

Site visitors use their "eyes and ears" for the CoA to assess whether and how the program recognizes the importance of cultural and individual diversity in professional psychology. They look at whether the program has and continues to make systematic, coherent, and long-term commitments to recruit and retain diverse students and faculty or supervisors into the program. They also look at the extent to which the program takes steps to ensure an encouraging, supportive environment appropriate to the education and training of individuals from diverse backgrounds. The team further assesses the program's incorporation of relevant knowledge and experience with culturally diverse individuals and issues into the science and practice of psychology.

### ***Student-Faculty Relations***

Site visitors assess whether the program is conducive to the formation of ethically appropriate relationships between the student body or trainees and the faculty or supervisors that enhance the quality of learning experiences. The team attempts to determine whether the faculty or supervisors are accessible to provide appropriate guidance and supervision to the students and if the program acknowledges students'

rights, advocates for the cultural and individual diversity among the students, provides students with written policies and procedures upon entering into the program, and documents all complaints and grievances filed against the program.

### ***Program Self-Assessment and Quality Enhancement***

Site visitors attempt to determine if the program is committed to excellence and enhancement of the quality in its training and supervision. The program should engage in continual self-study to assess the effectiveness of meeting its philosophical goals and objectives. The program should frequently review its goals and objectives in order to be congruent with an evolving body of scientific and practical knowledge that serves as the basis of psychology practice.

### ***Public Disclosure***

The program must publicly disclose information regarding the procedures and policies that underlie its training and education. The program should make available to the general public accurate and complete documents relative to its goals, mission statement, faculty, students, admission criteria, administration policies, research and practicum experiences, education and training outcomes, and accreditation status. As of January 1, 2007, for doctoral graduate programs, this information needs to include time to degree completion, program costs, success in obtaining internships, and attrition.

### ***Relationships With Accrediting Body***

The program is expected to demonstrate its commitment to the accreditation process by fulfilling responsibilities outlined in the *Guidelines and Principles for Accreditation of Programs in Professional Psychology*. It is expected to follow APA's published principles and policies, to inform the CoA of relevant changes to the program's philosophy or model of training, and to be in good standing with the CoA and APA in terms of financial and accreditation status.

### **Importance of Accreditation**

For students, faculty members, supervisors, university officials, administrators, state licensing boards, and

community members, the process of accreditation engenders a sense of assurance that the accredited program reflects a high level of quality in its philosophy, goals, implementation of its policies and procedures, and training and education. During their graduate training or education and required internships and optional postdoctoral residencies programs and specialization, professional psychology students and trainees invest a significant amount of money and time in obtaining their degrees and completing the required supervised experiences necessary for psychology licensure. It is important for them to choose a program that fosters a high standard of learning that will adequately prepare them to face the challenges of an entry level psychologist in the job market. By choosing an accredited program, students and trainees can be assured that their rights will be respected, they will receive a significant amount of guidance and supervision from faculty members and supervisors, and the program will continually review policies and curriculum so that it meets the demands of evolving scientific and practical knowledge.

An accredited program provides benefits to university officials and faculty members and to internship and postdoctoral supervisors and administrators. The accreditation process provides guidelines that, if followed, will help protect them from ethical violations and enhance the quality of their relationships with students and trainees.

The accreditation process engenders a sense of security, credibility, and trustworthiness in the community. Accreditation indicates that a program reflects a high standard of quality in the preparation of its psychology trainees to effectively meet the needs of the public. State psychology licensing boards look for licensure applicants to come from APA-accredited programs or to document an equivalent training and supervised experience.

Overall, accreditation reflects a standard of quality and accountability that protects the interests of students, faculty and university officials, internship and postdoctoral training institutions, psychology licensing boards, and the community.

## ACCREDITATION BY THE COUNCIL FOR ACCREDITATION OF COUNSELING AND RELATED EDUCATIONAL PROGRAMS

---

Accreditation of an academic program reflects the initiative of faculty, administration, and even students at an institution. Accreditation provides multiple benefits for these constituency groups, as well as for consumers, by establishing a professional curriculum and by attending to specific aspects of quality assurance and gatekeeping. Though no panacea, accreditation offers one means by which an institution, an academic program, and its graduates can verify to both public consumers and professional peers that a contemporary and quality program of study has been embraced and promoted.

Accreditation of most graduate-level academic programs is advanced through one of two routes, these

being (a) institutional accreditation or (b) specialty accreditation. The former is quite common for academic settings, because it fosters a measure of uniformity and standardization among otherwise disparate academic programs. Institutional accreditation has a rather lengthy history of implementation and is well known to citizens as well as educators. Institutional accreditation is frequently awarded by one of the six regional accrediting bodies recognized by the United States Department of Education (e.g., Southern Accreditation for Colleges and Schools, North Central Accreditation for Colleges and Schools).

By contrast, specialized accreditation has a somewhat less established history than institutional accreditation. Specialized accreditation involves review of a smaller unit than an institution by professional peers advancing a curriculum peculiar to that discipline. Examples of specialized accreditation are noted in the accreditation practices of the American Medical Association, the American Bar Association, and the American Psychological Association (APA). A significant aspect of specialized accreditation is its oversight by a voluntary rather than governmental body. Currently, such oversight is by the Council for Higher Education Accreditation (CHEA). Recognition by and affiliation with CHEA is an endorsement of the specific nature of the educational process for a profession. Thus, CHEA recognition of the Council for Accreditation of Counseling and Related Educational Programs (CACREP) represents both rigor and uniqueness for the specialized accreditation of counselor training programs.

### History of Counselor Accreditation

The establishment of CACREP in 1981 was primarily related to efforts from the Association for Counselor Education and Supervision (ACES) and the American School Counselor Association (ASCA), both divisions of the American Personnel and Guidance Association (APGA), the forerunner of the current American Counseling Association (ACA). This initiative from ACES was logical, because its membership was largely representative of counselor educators and supervisors involved in the development of new counselor practitioners in public school, higher education, and mental health sectors of the field. The 1973 document that propelled the accreditation movement was titled "Standards for Entry Preparation of Counselor and Other Personnel Services Specialists." This effort

reflected a consensus of opinion concerning both classroom and applied academic experiences necessary for the minimally prepared graduate of a counselor education program.

In its initial 1981 standards, CACREP established the three practice environments of School Counseling, College Student Personnel Counseling, and Community and Other Settings. Beginning in 1988, CACREP embarked on a different route of accreditation with the adoption of standards for the accreditation of graduate programs in mental health counseling. Subsequently, various other specialty tracks of accreditation were instituted, including college counseling; gerontological counseling; career counseling; marriage, couple, and family counseling and therapy; and student affairs.

Since its inception, CACREP has functioned as an agency apart from ACA control. The CACREP board has traditionally been composed of members affiliated with various divisions of the ACA. A notable exception in this regard has been the accredited track in community counseling, for which no divisional status has ever been established by the ACA or its predecessors. This situation is historically remarkable, because the majority of non-school accredited programs have been in community counseling, but no ACA or professional affiliate group representing this track has ever been among the composition of the board. Additionally, some professional identity and turf related difficulties emerged in the 1980s for the CACREP track in marriage, couple, and family counseling and therapy when compared with the specialty accreditation for graduate study in marriage and family therapy advanced by the Commission on Accreditation of Marriage and Family Therapy Education (COAMFTE), a CHEA peer of CACREP. Still, amid a history of evolution and refinement, the CACREP, according to Schmidt, steadily developed as the primary agency for the recognition of counseling as a distinct and viable discipline.

### **Curricular Requirements for Entry and Doctoral Programs**

One significant aspect of accreditation has always been the establishment of a minimum curricular experience for graduate study in professional counseling. The academic requirements for accreditation have historically been fashioned to reflect national standards for the field. Accreditation by CACREP is founded on

adherence to curricular requirements at both entry and doctoral levels of graduate study. With few exceptions, the master's degree reflects the minimal graduate degree level for accredited entry programs, though some programs feature the educational specialist as the entry-level degree. Such degrees are intended to prepare graduates for postgraduate supervision in their pursuit of independent licensure. Such preparation is typical for licensure in social work and in marriage and family therapy, unlike psychology, which traditionally relies on completion of the doctorate for independent licensure. Currently, the CACREP curricular requirements for entry-level programs include eight content areas, these being (a) professional orientation, (b) human growth and development, (c) social and cultural diversity, (d) career development, (e) helping relationships, (f) group work, (g) assessment, and (h) research and evaluation. Additional clinical requirements reflective of the national standards involve a practicum (minimum of 100 hours, 40 hours of which are to be in direct client service) and an internship (minimum of 600 hours, 240 of which are to be in direct client service). Both of these clinical experiences are to include regular weekly individual supervision as well as group supervision.

Accreditation of doctoral programs by CACREP reflects continuing but advanced preparation beyond the foundational curricular requirements in entry-level study. However, accredited doctoral programs feature unique elements of preparation such as (a) advanced supervised clinical practice (often in teaching roles), (b) formal training in supervision (c) quantitative and qualitative methodologies for conducting original research, (d) pedagogical practices related to counselor education, and (e) advanced course work in supplemental areas, often as doctoral minors.

The minimal curricular requirement for the various entry-level degree tracks ranges from 48 to 60 semester hours. The minimal curricular requirement for the doctorate is a total of 96 semester hours (including master's study). A significant aspect of doctoral work is the equivalent of the accredited master's degree as prerequisite to pursuit of the terminal degree. Just as with most other professions, a master's degree in a related peer discipline (e.g., social work, psychology) is not typically considered to be the equivalent to the accredited master's degree in counseling, meaning that in many cases, those wishing to pursue the doctoral degree in a CACREP-accredited program may

have to complete additional course work before beginning their pursuit of the doctorate.

### **The Accreditation Process**

Accreditation represents both a condition and a process of professional review. As with any form of review, accreditation by CACREP involves multiple layers of scrutiny, both internal and external. As an initial step, the faculty in a program conducts an internal review of their status relative to the requirements in the CACREP standards. In this process of internal auditing, a program often devotes years of review and revision to align its policies, practices, and procedures with the standards. The cumulative product in this initial step is the preparation and submission of a self-study for accreditation. The self-study is designed to provide summary evidence for the scrutiny of external review relative to the program's compliance with CACREP standards. Once they have been submitted, self-studies are reviewed by multiple CACREP board members. If the self-review passes these initial evaluations successfully, the next phase of accreditation review begins: This is an on-site team review.

Drawing from their familiarity with both the specialty tracks for which the program is seeking accreditation and the CACREP standards, an on-site visiting team comprising volunteer professionals arranges for travel to the institution. The charge of the team is to verify the statements from the self-study and to address any questions identified by the board members who completed the review of the self-study. During a visit that is typically 3 days in length, the on-site team interviews both institutional and community stakeholders as well as program graduates, field supervisors, and others. The exit report from the team features summary findings concerning standards the team believes to be met or not met, which will be reported to the CACREP board. The institution receives a copy of the team report and has the opportunity to submit a rejoinder for clarification or dispute concerning the report.

Board decisions typically involve review of the self-study, the team report, and the institutional rejoinder as the basis for an accreditation decision. If the decision is unfavorable, a program may request an appeal at the next board meeting. If the decision is favorable, a program may receive either 2-year accreditation (with a required interim report that

addresses progress in improvement on standards identified as deficient) or 8-year accreditation from CACREP. Maintaining accreditation requires an annual fee and an annual report concerning vital statistics and related information.

### **Accreditation and Counselor Credentials**

The CACREP curricular requirements serve as the foundation for certification by at least two professional bodies. The National Board for Certified Counselors (NBCC) is an independent organization that certifies counselors on the basis of their completed graduate study. Significant in this process is that the academic requirements for certification by NBCC mirror those of CACREP. Similarly, the National Credentialing Academy (NCA), established by the International Association for Marriage and Family Counselors, offers a national certification in family therapy based on a variety of academic options. Specifically, a graduate degree from the marriage, couple, and family counseling and therapy specialty track accredited by CACREP is one of these options available for national certification by the NCA.

As of May 2006, 48 state legislatures (and the District of Columbia) had established licensure for the practice of professional counseling. In all but a few of these states, the National Counselor Examination (NCE), developed by the NBCC, is a part of the formal examination process for licensure. Additionally, the majority of licensure states have adopted CACREP curricular content areas as the minimal academic requirements for licensure. In this respect, relocation to a new state and subsequent licensure as a professional counselor can be assisted when licensure bodies rely on a common curriculum of graduate study for their licensees.

An obvious benefit in completing an accredited entry-level program is a seamless transition into doctoral study. Additionally, doctoral graduates are prepared specifically to function as advanced practitioners, researchers, or educators in the field of counseling.

### **A View to the Horizon**

As of May 2006, CACREP had accredited 202 institutions. Of these, one was Canadian (University of

British Columbia) and one offered a totally online training program (University of Phoenix—Phoenix and Tucson campuses). Each of these 202 institutions had at least one accredited entry-level track and 49 had accredited doctoral programs. According to CACREP, the prominence and professional viability of accreditation of counselor training programs has been steady and impressive during its initial 25 years of existence.

In its draft documents for the 2008 standards, CACREP's Standards Revision Committee has considered a variety of pending changes, including (a) merging community counseling and mental health counseling into a single entry-level track, (b) deleting the specialty track in gerontological counseling, (c) merging the college-oriented specializations, (d) requiring program faculty hired after 2008 to be from counselor education programs (a requirement similar to that of the APA for faculty composition in an accredited program), and (e) adopting a competency-based orientation for accredited programs. In this respect, revision efforts for CACREP standards reflect a continuation of the contemporary issues affecting the professional practice of counseling.

CACREP has also begun the revision process for organizational aspects other than accreditation standards. Specific changes discussed in the spring 2006 newsletter (*The CACREP Connection*) by then-Chair John Culbreath were (a) an application process to select an independent board composed of persons unaffiliated with an ACA divisional interest, (b) an expanded vision of international accreditation of counselor preparation programs, and (c) a reexamination of the organizational name, particularly related to "other educational programs." Additionally, sustained and successful discussions have begun between CACREP and the Commission on Rehabilitation Education (CORE) on unifying these counselor accrediting bodies. These and other evidences indicate that the horizon looks quite promising for a 21st-century version of CACREP to be focused on curricular advancement and refinement as well as organizational vitality and relevance.

McGlothlin and Davis note that the benefits of accreditation to the student are demonstrated in terms of acquired knowledge for formal credentialing (e.g., certification, licensure), demonstrated competency for practice, and participation in professional acculturation for identity. As a form of specialized

accreditation, CACREP offers a formal means of assuring quality preparation for the practice of professional counseling.

## ADULT DEVELOPMENT

---

Along with aging, human development occurs. Contemporary definitions characterize development as systematic changes and continuities in the individual that occur between conception and death. Development is implied to be predictable and continuous with pattern and order. Counseling is developmental and strength-based, and the counselor aids an individual, couple, or family through normative developmental adjustments and transitions. Because counseling is concerned with normative stresses, adjustments, and life transitions, rather than pathologies of the individual, knowledge of development is essential.

### The Nature of Development

The developmental process occurs at psychological, biological, and social levels. In psychological development, the perceptions of a person change, as do other mental processes. Biologically, a person's body and organs tend to decline in efficacy while aging.

The social aspect of development includes interpersonal relationships and skills and roles played in the larger society. A developmental approach examines the interplay of environmental and individual factors on a person. Developmentally, a person is always in the process of change, influenced by the interplay of outside influences on his or her life.

Maturation and learning are the two processes that underlie developmental change. *Maturation* is the biological unfolding of the individual according to the heredity of his or her parents and the passing on of genes. *Learning* is the process through which experience brings about changes in a person's thoughts, feelings, and behavior. Development occurs in historical and cultural context that influences the rate and intensity of how an individual's development occurs. A broader context for discussing adult development follows; it examines some early influences on the developmental perspective.

### Historical Synopsis

According to some, developmental psychology began nearly 4 centuries ago, as evidenced in the works of literary artists, like Shakespeare, who viewed development as extending beyond adolescence, well into adulthood. In the 20th century, others began to think of development as continuing throughout a person's life. The objectives were to measure changes over a person's life span rather than to focus on the process of change itself.

Developmental systems encompass the entire life span of the individual and offer evidence that development in a person proceeds by stages. While there are several theories of human development that agree on some points and disagree on others, development is not so much a single theory as it is a way of looking at a person's life, in which theories can be integrated within a framework. The shift to a life-span view of the developing individual was solidified with the developmental perspective of Erikson, who sought to understand the psychosocial challenges confronting the individual at each stage of life. Building on Freud's ideas, Erikson and others broadened the developmental perspective by including psychosocial trends evidenced by a crisis or turning point in each stage of human development. This shift resulted in a renewed focus on issues related to the "whole" individual, including such factors as spirituality, family

environment, socioeconomic considerations, and the impact of groups on the individual's developmental process.

### Theories of Adult Development

The primary tension in theories of adult development is between the *ontogenetic* perspective, which posited that developmental forces are internal and biologically based, and the *sociogenic* perspective, which argued that change in adulthood is due primarily to social influences. Ontogenetic proponents were mostly from Germany, while the sociogenic proponents were influenced by French sociologists, such as Durkheim. One person who may be classified as part of the ontogenetic school of thought was Freud. Freud published a number of works emphasizing the role of sexuality in human life. Influenced by the philosophers of his era (i.e., Schopenhauer and Nietzsche), Freud saw human beings as guided by passion as well as reason. Freud went beyond the traditional Victorian views of sexuality by identifying such theories as the Oedipus complex (named for the legendary king of Thebes who killed his father and married his mother) and the Electra complex (named for the mythological Greek who avenged her father's murder by killing her mother). Freud disclosed in conceptual terms what literary poets had espoused all along and stated those themes in mythopoetic terms. Even the naming of the two aforementioned theories was indicative of how Freud's character was influenced by the passionate figures in mythology as well as of his own passion to become an intellectual force in his own right.

### Ontogenetic Models

Ontogenetic models posited that development consisted of stages that are universal, sequential, and irreversible. Ontogenetic theorists, such as Buhler, Jung, Levinson, and Maslow modified Freud's psychosexual theory to a psychosocial model. Neo-Freudians, such as Adler, suggested that siblings are significant in development. Jung claimed that adults experienced a midlife crisis, which could lead to a liberating effect on an individual's personality in adulthood. Horney challenged Freud's ideas about gender differences, and Sullivan demonstrated how early relationships in life could set the stage for styles of relating in adulthood. Perhaps the person who most influenced life-span

development was Erikson. Erikson concerned himself with the inner dynamics of personality and proposed that an individual's personality evolved through systematic changes. His *epigenetic* approach to human development assumed that development was the result of interacting genetic and environmental elements.

Piaget believed that individuals' innate intellectual development helped them adapt to their environment. He posited the concept of *constructivism*, claiming that individuals actively construct new understandings of the world based on their experiences in development. As an individual developed, he or she constructed a more accurate understanding of the world.

### **Sociogenic Models**

Sociogenic models of adult development sought to balance a completely innate, and thus predetermined, perspective of human development with a perspective that individuals have an influence over their own development and are not completely subject to events out of their control. One sociogenic model is the *disengagement theory*, which posits a mutual withdrawal between the individual and society as one ages. This was countered by the *activity theory*, which posited that the more active a person is as he or she ages, the better quality of life experienced. These theories were integrated by Havighurst, Neugarten, and Tobin, who sought to demonstrate that the factor that determined the level of activity among individuals as they age was personal desire.

Watson believed that learned associations between external stimuli and observable responses were the building blocks of human development. A basic tenet of Watson's behaviorism theory was that observations of behavior, rather than speculations about unconscious motives, should be the foundation of theory. Watson stressed the importance of learning in human development to the point that nurture was dominant and nature counted for little.

A proponent of the sociogenic model was Bandura, who posited a social learning theory of development. His theory suggested that humans were cognitive beings whose processing of information from the environment had a major influence on their human development. *Observational learning* from other people, or models, was the primary way in which a person changed his or her behavior. Aldwin and Gilmer sum it up this way: "According to these

theories, change in adulthood is characterized by a succession of role transitions that are shaped by the immediate social context and larger social structure rather than by internal psychological processes alone" (p. 58).

### **Multidimensional Models**

Many theories attempted to provide middle ground between the ontogenetic and sociogenic perspectives by integrating biological, psychological, and spiritual influences on development. One such theorist was Bronfenbrenner, who felt that many developmentalists assessed human development out of context. To counter this thought, he formulated the *bioecological* approach, which took into account biological and psychological changes of the individual interacting with the environment. From this perspective, people were not just passively subjected to outside influences; they shaped their physical and social environments while also being shaped by the cultural environment they helped create. Development was something that individuals *do* rather than something that simply *happens* to them. These theories proposed an increasing liberation from social and biological conditioning of adult development.

### **Holistic Models**

More recently, the counseling field has devoted increased attention to *wellness* as a theoretical approach to human development. Wellness includes physical, intellectual, social, psychological, emotional, and environmental factors and is a way of life oriented toward optimal health and well-being, in which body, mind, and spirit are integrated by the individual to live life more fully within the community. The Wheel of Wellness model was based on Adlerian theory, and incorporates aspects of gender and cultural identity.

Systems theory was based on the work of biologist von Bertalanffy. He saw the essential phenomena of life as individual entities called organisms. An organism was defined as "a form of life composed of mutually dependent parts and processes standing in mutual interaction" (Bertalanffy, 1968, p. 33). All living systems operate on a similar set of principles, which means they are internally interdependent. Proponents of systems theory conceptualized a system (e.g., an individual, a couple, or a family) as a whole consisting of interrelated

parts, each of which affects and is affected by every other part, and each of which contributes to the functioning of the whole. Development takes place simultaneously and interdependently amongst each member of the system, and each person's development affects the development of the other members.

### **Transpersonal Models**

A *fourth force* (a term originally coined by Maslow) emerged in counseling to capture a more complete perspective of the individual in development. Recently this approach has been receiving more attention; its central theme is inclusive, but it still values diversity and unity. Early theories focused on the individual's problem behaviors and cognitions. Wellness models attempted to embrace a person's differences while facilitating a balanced way of life for an individual. More recently, developmentalists have been examining a broader perspective of development. This view of transcending (*trans* meaning in this case *beyond*) human differences was an attempt at revealing what unites all persons, from the subatomic level to the physical level to the spiritual level to stages of consciousness and beyond. Transpersonalism is concerned with the study of humanity's highest potential and with an individual's essential nature of being. This is an attempt to focus on what unifies individuals as spiritual beings while respecting a person's biological, ethnic, religious, and other differences.

The fourth force, which also emerged from mainstream psychology, is concerned with states of consciousness, identity, spiritual growth, and levels of human functioning *beyond* those commonly accepted as healthy and normal. It integrates Eastern perspectives on human development with Western psychological perspectives. Such influential views of the stages of consciousness were proposed by Aurobindo and Maharshi, both Indian sage-philosophers who proposed developmental views of human consciousness and enlightenment.

Perhaps the seminal effort in the study of consciousness in Western psychology was provided by James, who is arguably the father of transpersonal psychology. His interest in spiritualism and introspective studies of consciousness set him apart from his colleagues who were in favor of the prevailing positivistic view of his time, that knowledge was limited to observable facts. James identified mind with consciousness and called it a *stream of consciousness*.

A more current model was proposed by Wilber, who posited an integrative and developmental model of human development and consciousness. Wilber asserted that different developmental schools have often clung to one school's logic while ignoring the validity of other perspectives. Consciousness poses a challenge to some developmentalists because of the difficulty in reducing and measuring a person's consciousness in a traditional observable method. Wilber argued that consciousness has been reduced to personal structures, and that its study has focused merely on altered states of consciousness, while no coherent theory of the development of consciousness has emerged. What Wilber calls *integral psychology* is the goal to honor and embrace "every legitimate aspect of human consciousness" by using a logic of inclusion, networking, and what he calls *wide-net casting*.

### **Future Directions**

Counseling's view of development continues to expand as more information becomes available concerning the complexity of human life and the urgency to meet the changing needs of society. While transpersonal counseling means to go "beyond the personal" or beyond a person's conditioned personality, it seeks to reveal and develop a person's identity in a broader, more unified whole. The parallels between modern physics and transpersonal philosophies have been noted for many years. For instance, there is a connection between Western science and what has been described for thousands of years by the philosophical traditions of the Far East.

Quantum theory has eradicated the idea that objects are fundamentally separated and views the entire universe as an interconnected web. Another principle of quantum physics is the *observer effect*. Simply put, there is a dynamic interaction between the observer and what he or she is observing, to the point that the observer influences change in that which is being observed. From a developmental perspective, this confirms the Eastern view that people are participants in creating their world. A transpersonal counselor would have the view that a person's attitudes, expectations, and beliefs create the reality that he or she experiences. As the field of counseling continues to mature and our knowledge of human beings expands beyond the physical realm, counselors also must explore and examine their own development in

order to continue to accommodate the needs of a diverse world.

## ADVENTURE THERAPY

---

Adventure therapy is an active and creative form of group psychotherapy that employs experiential

activities designed to promote desired therapeutic outcomes for clients. Adventure therapy is a broad rubric that subsumes a variety of experiential approaches to group therapy that utilize challenging, cooperative tasks to foster healthy change in clients. Examples include experiential outdoor counseling, adventure-based counseling, wilderness therapy, and residential camping. It is often, though not always, conducted in outdoor or wilderness settings, and it is closely related to the fields of therapeutic recreation and outdoor education. While careful assessment of the problems that clients bring to therapy will inform the specific interventions that skilled therapists choose to employ, adventure therapy is a solution-focused approach that emphasizes group members' individual and collective strengths and resources.

### History

The use of group activities as the primary agent of psychological change emerged with J. L. Moreno's psychodrama innovations in the 1920s, and several modern experiential approaches to psychotherapy emphasize the use of an activity base, including art, music, and play therapies. The therapeutic effects of natural settings were evident in the camping programs developed for troubled youths in the 1930s. Outward Bound, the experiential learning program developed by Kurt Hahn in the 1940s and brought to the United States in the 1960s, effectively inspired self-discipline and self-confidence through physically and mentally challenging experiences in wilderness settings. The principles of experiential learning developed in the Outward Bound schools were later adopted and further developed by organizations such as Project Adventure and the Association of Experiential Education. These and similar organizations adapted the survival challenges of the Outward Bound protocols to nonwilderness settings in schools, recreation centers, and physical and mental health treatment centers by developing challenge courses, high and low ropes courses, cooperative games, and initiatives designed to elicit learning through experience. Today, the principles of adventure therapy are evident across a wide range of programs, including personal growth and enrichment curricula, corporate training and teambuilding efforts, antirecidivism programs for adjudicated youth, substance abuse treatment, and both outpatient and inpatient mental health counseling for families, couples, and individuals.

## Nature of Adventure Therapy

The fundamental proposition of adventure therapy involves exposing a group of individuals to a novel setting in which they strive to negotiate a variety of challenging tasks that involve real or perceived risk and where the outcome of their efforts is directly affected by the choices that they make, both individually and in concert with other group members. The settings of adventure therapy often involve the natural surroundings of the outdoor environment and usually entail adventurous activities inspired by such outdoor pursuits as rock climbing or wilderness survival. Confronted by the real or perceived risks—both physical and psychological—inherent in the challenges posed by these activities, clients experience reactions consistent with their preferred or characteristic affective, cognitive, and behavioral responses when confronted by difficult situations in their everyday lives. Thus, they have an opportunity to “catch themselves being themselves.” As clients process their experiences with the group by sharing their experiences and receiving feedback from the other members, they have an opportunity to gain insight about their choices and about the consequences of their behavior. As the activities of the group proceed, they may choose to enact new behaviors that they believe will be more likely to produce the outcomes they desire and thereby they gain an experience of positive behavioral change. The goal of adventure therapy is to assist clients to transfer what they learn from the novel experiences of these adventurous initiatives to the more significant domain of their daily lives.

The challenges that confront group members in therapy serve as metaphors for the challenges they must negotiate in everyday living. The metaphoric content of the cooperative games, outdoor pursuits, and challenge initiatives employed in adventure therapy may be implicit or explicit. Implicit metaphors may vary among individuals in a therapy group and emerge when the group therapist or facilitator elects to allow an experience to speak for itself.

However, group leaders will often choose to explicitly frame the metaphoric content of an activity using a procedure known as *frontloading*. Frontloading involves introducing an activity or initiative to the group using a metaphoric theme related to the treatment issues of the members. Clients then draw parallels between the completed activity and challenging experiences in their lives; this process allows them to more readily transfer the learning they gained from

the experience to their lives outside of therapy. Such a transfer of learning gained from a specific experience to more general life experiences is known as an *isomorphic connection*.

The process of forming isomorphic connections is furthered by the structure of the adventure therapy experience. In addition to frontloading the metaphoric content of activities, adventure therapists also carefully choose the *sequence* of challenge initiatives they present to the group in order to encourage a sense of commonality or cohesiveness within the group, to foster trust among the members, and to build upon the successful experiential learning of earlier activities. In addition, adventure therapists also assist members to *debrief* or process their experiences after the group has completed an activity or whenever an opportunity arises to gain from something experienced by the group. Frontloading, sequencing, and debriefing are processes that shape the fundamental structure of adventure therapy, intended to enhance the transfer of positive behavioral change gained through therapeutic experience in order to help clients achieve the treatment goals established at the outset of therapy.

## Effectiveness and Efficacy

While a wealth of anecdotal evidence would support the treatment effectiveness of adventure therapy, very little empirical research exists in the professional literature concerning the efficacy of this experiential approach to group psychotherapy, and few conclusions can be drawn from the studies that do exist. Support for modest positive treatment effects across a range of adventure programs can be found in peer-reviewed journals; however, few studies examine therapeutic techniques, and well-controlled outcome research for various forms of psychopathology do not exist. There is no well-defined or broadly accepted treatment methodology for conducting therapy using adventure-based activities; therefore practitioners and researchers have little guidance as to which activities or settings might effectively treat particular client concerns.

Despite the absence of substantial research support, many programs exist that offer adventure therapy to clients with a broad range of problems and concerns. The ethical constraints of professional group practice demand that practitioners be competent to provide the interventions they offer to their clients, and individuals interested in adventure therapy can obtain training in numerous programs of study in the

fields of counseling, psychology, and social work as well as supervised practical experience in a variety of therapeutic settings. Experienced practitioners currently enjoy numerous resources to assist them in providing adventure-based initiatives to their clients. Adventure therapy is a creative and attractive alternative to traditional talk therapies for both clients and therapists alike. The competent application of this experiential approach appears to have the potential to enhance a client's experience of the therapeutic process and to promote lasting, positive change.

## AGING

---

Although aging is a topic that applies to everyone, it tends to be a mysterious process, often leading to more questions than answers upon thoughtful reflection. It may be that we know it when we see it, but little agreement exists in terms of definition, explanation, understanding, or relevancy to oneself.

Old age is typically defined as any age over 65 years, although this number is an arbitrary cutoff. With the increasing life span, additional terminology or definitions have appeared. Gerontologists, professionals who study aging, refer to adults over 65 but under age 75 as the “young-old,” those age 75 to 85 as the “old-old,” and those over age 85 as the “oldest old.” However, aging may be best understood when placed within a cultural context, as life expectancy varies greatly around the world. Today, the life expectancy in most industrialized countries is well over 70 years of age and increasing. Seven percent of the world's population is currently over the age of 65; by the year 2030, this figure is likely to more than double.

Life expectancy in the United States has increased dramatically over the past two centuries with advances in medicine and public health. Today the average life expectancy at birth is approximately 74 years for men and 80 for women. The “graying of America” has become a popular phrase in reference to the drastic changes occurring in the U.S. population demographics. Although one out of every eight Americans is currently over age 65, with the baby boom cohorts aging, the elderly population is projected to reach 70.3 million in the next decade, making up 20% of the population. Estimates indicate that by 2030, one out of every five Americans will be over age 65, with racial and ethnic diversity continuing to increase with the population expansion.

Historically, the aged or oldest members of a community were held in high esteem and valued for their wisdom and knowledge. However, in modern society, there are many myths and stigmas attached to

growing older, leading to what gerontologists identify as ageism. The term *ageism* refers to prejudice or discrimination against an individual because of age, and it tends to be facilitated through the use of stereotypes to categorize the elderly. Older people are often thought of as weak, fragile, senile, asexual, and incompetent. Research suggests that some stereotypes are so prevalent that they affect older adults' performance on memory and performance tasks as well as reports of self-esteem.

Regardless of myths, aging is an ongoing process affecting those fortunate enough to avoid the alternative and experience the full life cycle. With people living longer and healthier lives, more focus is being given to the topic of aging than ever before.

### **Psychosocial Theories of Late Adulthood**

Many theories have emerged to explain the psychosocial development of late stages of life. Although there are multiple theories available, the majority fall under one of three categories, depending on the general aspects of adult development focus.

#### ***Core Self Theories***

Identity theories stem from the concept that adults strive to achieve their full potentials, and that each person must depend on him- or herself to achieve that goal. Much work in this area comes from Erikson's stages of development; this concept posits that in times of transition, individuals struggle with issues of identity and role confusion. Erikson postulated that in the final stage of life, people work toward integrating their own life experiences with their vision of society and the future.

Core self theories hinge on the idea of optimization of goals through compensation, meaning that individuals both assess their goals and identify how to achieve their goals despite personal difficulties. These theories tend to be supported by behavioral genetics, suggesting that some inherited traits are more apparent later in life. An example would be temperament, which remains constant across the life span.

#### ***Stratification Theories***

Stratification theories purport that how people are divided into social strata (e.g., age, gender, ethnicity,

sexual orientation) influence their access to various options, which can then have an impact throughout the life span. Some theories focus explicitly on the impact that age plays in shrinking an individual's social sphere, thus leading to social withdrawal. Another theory states that the elderly remain socially active but are forced into withdrawal due to ageism. However, the stratification theories are best viewed through a lens of multiculturalism. Given that cultural values and social categorization are present from birth throughout the life span, they presumably affect life paths.

#### ***Dynamic Theories***

In contrast, dynamic theorists focus on individuals and the world they inhabit, suggesting there are daily changes in late adulthood. A life of adaptive changes is assumed as people strive to maintain their core selves within the context of a changing body and world. These theories are based on the position of ongoing, nonstop changes in the self and the world, but it is assumed that people will adapt to changes in a way that maintains the core of who they are.

### **Physical Changes in Aging**

The most overt changes of aging may be those that are physical in nature. Much like psychosocial development, physical aging has been explained by various theories, with two basic postulates emerging. Although both focus on the adaptations of the human body, one defines aging as a predetermined, natural part of a fixed genetic plan, with the other examining aging on a cellular level and identifying the cause of aging through interactions with the environment.

#### ***Genetic Aging***

The genetic theory of aging is based in information about life expectancy, noting that every species seems to have a maximum life span, with this being approximately 120 years for humans. According to genetic explanations of aging, all people inherit genes that allow for survival until middle age or through the reproductive years. Genes causing aging are then activated, with illness and death each occurring in a specific genetic way. Even without the genes for various diseases that occur later in life, there may be several genes that cause aging directly. Some theorize that death could be an adaptive way to make room for a new generation.

### **Cellular Aging**

Theories that emphasize aging at the cellular level state that cell duplication allows for aging as minor errors accumulate over time. Often referred to as damage-based theories, aging is thought to be caused by mutation caused by stresses or toxins or occurring in the processes of cellular repair. Other possible causes of errors on the cellular level may be the presence of oxygen free radicals, deficiencies of the immune system, or telomere shortening when cells no longer reproduce. These cases of imprecise replication, and the cells' decreased ability to detect and correct them, can result in harmless changes, minor reductions in function, or fatal damage. The processes by which cells are able to repair and replicate themselves are believed to become less successful with age.

### **Appearance**

Physical appearance may be the most concrete indication of aging. The first outward signs of aging are typically seen in the skin, as aging skin becomes drier, thinner, and less elastic. There may also be an appearance of age spots, blood vessels, and wrinkles in the skin. A change in hair color and texture is a common sign of aging, with hair tending to thin and turn gray and then eventually white.

Changes in body shape and musculature also occur with age as people become shorter in late life due to settling of the vertebrae. Body shape also changes as body fat redistributes and collects in the torso, abdomen, and lower face. Regardless of the fat redistributed, there can be an overall weight loss occurring with age due to loss of muscle and even bone, leaving older people at risk for falls. Remaining as physically active as possible helps aging adults to protect themselves from serious losses of muscle or bone.

### **Dulling of the Senses**

Because our senses allow us to connect with other people and the world around us, these changes can be devastating if the losses are not compensated for. Sensory deficits can limit an older adult's ability to interact socially and perhaps cause an accelerated process of withdrawal and isolation. Only 10% of the elderly have adequate vision. Although some aging individuals can correct their vision with glasses, a substantial portion suffers serious vision problems

due to cataracts, glaucoma, or macular degeneration. Another sensory deficit common in older age is that of hearing loss. One-third of individuals over 60 have hearing loss, with one out of two adults over the age of 80 suffering from poor hearing. For many people this can be helped with the use of hearing aids, but it may be difficult to compensate for if loss is severe.

### **Sexual Response**

Changes in physical appearance and sensory acuity may feed the stereotype of the elderly as asexual. However, research indicates that intimacy and sexuality are an important part of healthy relationships throughout the life span. One age-related physiological change is that of the slowing of the sex response cycle. It may take a man longer to attain an erection, and it may take longer for a woman to attain sufficient vaginal lubrication for intercourse. An erection may not be as firm as it was at a younger age, nor will the vagina have as much elasticity. It may also become more difficult for both men and women to achieve orgasm. However, contrary to popular belief, these changes do not signal the end of a satisfying sex life, and many older adults enjoy intimacy and physical contact throughout the life span.

### **Common Health Problems Associated With Aging**

Poor physical health is not an inevitable consequence of aging. Unfortunately, many illnesses go undetected and untreated because older adults mistakenly blame symptoms on the aging process. Through prevention, early detection, and treatment, many health problems can be avoided during later years of life.

Arthritis, a painful, chronic stiffening of joints, is common in the United States, with over one half of adults over the age of 65 suffering from this disease. Diabetes, caused by blood levels of glucose being too high, can lead to dangerous health problems in older adults, including kidney failure, vision loss, and neuropathy. Although cancer can develop at any age, older adults are also more likely to experience this disease.

Osteoporosis, often considered a "silent" disease because symptoms may not be initially noticed, weakens the bones, increasing risks for a fracture or break. Although osteoporosis is more common in women, many men also encounter weakening bones. In addition, men over the age of 50 may be at risk for prostate

problems. Not caused by aging in itself, urinary incontinence, or the loss of bladder control, can range from mild to uncontrollable in older adults.

High blood pressure, or hypertension, is often referred to as the “silent killer” of the elderly due to the lack of identifiable symptoms. However, left unidentified or treated, high blood pressure can lead to stroke, heart disease, and kidney failure. Strokes, the third leading cause of death after heart disease and cancer in the general population, occur when blood is unable to flow to a part of the brain; this causes cells to be damaged or die. In an aging individual, strokes are a leading cause of physical and mental disabilities.

### Cognitive Decline

Research consistently supports observations of decrease of memory and speed of thought processing with age. However, there appears to be little agreement on the specific domains or timing of cognitive decline. Although few 80-year-olds would deny change in their cognitive functioning compared to when they were 40, cognitive change is characterized by individual differences. For some people, decline occurs rapidly and appears extreme. For others, decline may be a slow and gradual process or may not appear to occur at all until late life. The dulling of the senses that occurs with aging may have an impact on cognitive processes as the brain may receive distorted sensory input. However, if input reaches the brain, memory can be quite good, although speed of retrieval may be slower due to decreased processing speeds. It seems that cognitive decline in late life is not as extensive or as devastating as was once thought.

### Dementia

Dementia is defined as a chronic decrease in memory in addition to impairment in at least one other area of thought process, including impaired judgment, problem-solving ability, emotional regulation, or language ability. There are more than 70 diseases or circumstances that can cause various forms of dementia, all characterized by forgetfulness and confusion. In general, dementia is a product of damage to the brain and can be reversed less than 5% of the time, depending on the circumstances (e.g., brain tumor or injury, stroke, incorrect medication, or other head injury). Dementia should not be confused with delirium, which is a rapid onset of decreased cognitive ability

such as altered consciousness or impaired memory, but which abates with treatment of underlying cause.

The most common form of dementia is due to Alzheimer’s disease. This cognitive decline is not part of the normal aging process but is defined as a gradual loss of memory and personality. Vascular dementia is the next most common type of dementia, leading to cognitive decline through one or a series of strokes. This dementia causes sporadic and progressive loss of cognitive functioning. Some dementias, such as Parkinson’s disease or Huntington’s disease, tend to begin with motor deficits and produce cognitive deficits only in the later stages of the disease process.

An important aspect of the dementia literature addresses the challenges faced by those caring for individuals suffering from dementia. Caregivers are encouraged to seek information and support, given the taxing nature of caregiving for a person with dementia.

### Future Directions

Although there is no denying that change occurs over the life span, aging is not synonymous with disease, frailty, decline, or unhappiness. Many older adults would say that they continue to thrive and find meaning in their lives well beyond the age of 65; some would say life didn’t start until they turned 70.

More than ever before, focus is on the process of healthy aging. Contemporary approaches to aging highlight the optimal physical, mental, and social well-being or functioning of older adults, with clear intentions for the quality, and not simply the length, of life continuing to improve. One thing is certain—as long as it continues to occur, aging will be a journey of continued interest and exploration.

## ALCOHOLICS ANONYMOUS

---

Alcoholics Anonymous (A.A.) is an organization created in 1935 by two men who had a desire to stop drinking and become sober. Today, this group offers friendship, understanding, and hope to other people struggling to recover from alcoholism. The A.A. organization is based on the Twelve Steps. The only requirement to join is a desire to stop drinking. Alcoholism has long been the common denominator for many social ills, affecting areas of personal finance, legal status, personal and business relationships, and long-term health. Unlike programs in the self-help movement, A.A. is focused on mutual help.

### The A.A. Philosophy

A key to their philosophy is that A.A. views alcoholics as lacking the ability to control their drinking once they begin and that help outside the self is needed to gain and maintain sobriety. Although A.A. and its members do not seek out alcoholics who would benefit from A.A., they espouse the notion that those who seek help must be taught that alcoholism cannot be cured, but it can be treated via total abstinence. The typical path of A.A. participants is to first hit rock bottom because of their drinking habits, then to attend A.A. to become sober, and then to continue in a state of recovery by attending A.A. meetings.

### A.A. Meetings

It is in the A.A. meetings where the therapeutic value of talking comes into play; talking topics are limited to those relating only to alcohol. Meetings generally include a recitation of the Twelve Steps, a motivational

speaker (usually a member), and the Serenity Prayer. Outside of these core elements, the meetings are quite autonomous in that they are member driven, and each group creates its own culture and traditions.

The meetings are designed to offer each member an outlet to talk about personal alcohol-related experiences and to hear the stories of others; the therapeutic value of such talk has been the core of the program. The interpersonal climate of the A.A. meeting is one that typically encourages relationships based on the common goal of abstinence. In addition, the meetings offer members a place to meet new friends, hear inspirational speakers, and socialize in an alcohol-free environment.

The open meetings allow for anyone to attend with the pledge to not reveal the names of the participants. The closed meetings are only for A.A. members so they can discuss problems and situations that are specific to alcohol; closed meetings also give the newcomers opportunities to ask questions of veteran A.A. members. A.A. meetings are available in most towns and cities all across the United States and in 150 countries.

A.A. meetings in an online environment are the most recent advancement and source for support. Online meetings exist for convenience and for those who are unable to attend meetings due to geographic locale, or physical inability to attend due to lack of mobility.

Eighty-six percent of A.A. members belong to a home group, which is the meeting group they primarily attend; this group is where the member volunteers time, gives support, makes friends, and receives support from other members. In addition to attending meetings with the home group, A.A. members often seek out and attend meetings when they are away from home. Listings of A.A. meetings are found in newspapers, A.A. booklets, and through word of mouth. Often groups are formed based on demographics or particular needs; these include meetings for beginners, women only, men only, gay or lesbian individuals, nonsmokers, and Spanish speakers, to name a few.

Medical and mental health professionals, the courts, and clergy often recommend A.A. to problem drinkers. However, A.A. is not affiliated with any church, prison, or institution.

### Sponsorship

A.A. advocates and encourages new members to seek out the guidance of a sponsor, someone who has been

in the program and worked through the steps. Seventy-eight percent of A.A. members have a sponsor, and the majority of those sought out sponsors within the first 90 days of joining A.A. Sponsor relationships can be long- or short-term and may change over time depending on the needs of the member. These volunteer sponsors are not counselors but rather mentors or coaches; they are supportive by responding when requested, but they do not give advice. The sponsor-based relationship can become very personal and for many is the key to staying sober and continuing to attend meetings. Sponsorship helps not only the A.A. member in need but also the sponsor, who finds it therapeutic to help someone else through a difficult time.

### **Al-Anon and Alateen**

Separate organizations exist for those people touched by alcoholism in one form or another. These groups comprise parents, spouses, children, friends, or anyone who has a connection with a problem drinker. Members attend sessions similar to A.A. meetings, where they share their experiences in a safe and healing environment, and they can join in discussions or be silent depending on their needs. Whether or not the person with the drinking problem attends A. A., these meetings are a place to go for help and hope. Concerns about drinking, relapse, deception, money problems, self-esteem, threats, public embarrassment, abuse, anger, and many other topics are shared by people who have first-hand experience dealing with alcoholic significant others. Like A.A. meetings, Al-Anon and Alateen meetings are free and their locations can be found in the phone book, through A.A., or online.

### **Downside to A.A.**

As is the case with any organization, not everyone finds the good experienced by those who succeed in and continue to stay with A.A. A 1998 federal study found that just 26% of clients seeking treatment for addiction had problems only with alcohol, so many A.A. members may be faced with dual addictions (e.g., to cocaine, heroine, marijuana, or methamphetamine as well as to alcohol). These members may be particularly vulnerable to relapse and are encouraged to seek out other 12-step programs.

Some A.A. members are coerced to attend meetings; according to A.A.'s *2004 Membership Survey*, 11% of their clientele attend meetings because of a

court order. Coercion to attend meetings goes against the premise and criterion that to belong to A.A. one must have the desire to stop drinking alcohol. Other forms of coercion come from family members and employers. There are no statistics to determine the continued success of those who were introduced to A.A. under coercion.

The core A.A. requirement of total abstinence comes from the belief that one drink inevitably leads to another and another. The debate between models of total abstinence and controlled drinking has raged for decades; the opinion of A.A. leaders and counselors is unyielding. Younger people and those with a shorter history of problem drinking are more apt to strive for controlled drinking instead of total abstinence.

The implied belief in God, a higher power, or some notion of spirituality (step 3 in the 12-step plan) is another reason some resist A.A. However, A.A. proclaims that there is no requirement to believe in any spiritual entity to be successful in A.A. but rather to know that success cannot be achieved on one's own. Other elements of receiving help outside of the self include sponsors, therapists, medical assistance, role models, and nondrinking friendships.

Another criticism of A.A. is that it does not address the medical side of alcoholism. The *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV)* states that alcohol withdrawal occurs with the termination of heavy and prolonged alcohol use; such use is typical of a new A.A. member. Although A.A. acknowledges that alcoholism is a disease and that medical problems stem from withdrawal, it does not employ professionals to assist with alleviating the physical pain associated with the cessation of alcohol.

### **A.A. as a Counseling Strategy**

Knowledge of A.A. and what it has to offer may be a therapeutic bridge for clients who have questions and concerns about this path. Counselors' familiarity with A.A.'s Twelve Steps and the core beliefs and expectations of members may serve well the alcoholic or problem drinker who is searching for the strategy that works best for him or her.

Knowing where a client is in the alcoholism treatment process and what A.A. has to offer provides another option to improve the client's life situation. Counselors may attend open meetings to get a sense of the diversity, problems, and life issues discussed in

local groups and how they might meet the client's needs. Familiarity with the tools offered and the benefits of Al-Anon and Alateen groups may also be helpful when referrals are requested.

Encouraging clients to attend meetings where they can openly discuss their feelings with others in similar situations may lead to their empowerment and increased self-esteem. Healing properties that exist in groups include members who admit defeat while they still attend meetings and offer hope to newcomers. Positive and uplifting communication behaviors are evident as members allow hidden feelings and emotions to be shown to others where they can be worked through in a safe environment. Stories are shared without shame, and members learn from each other as all the stories blend together. A sense of understanding, friendship, and care evolves as members tell their truths and share their wisdom with each other.

Group counseling is a powerful tool for clients who are struggling to face each day without alcohol in their lives. Knowing they have a circle of people, including their sponsors who understand their dependency and despair and other members who have been in that situation before, allows them to become and remain sober. Being part of an empathic group where members all share the same goals of fighting alcoholism may instill a sense of harmony in a previously chaotic world.

### A.A. Twelve Steps

1. We admitted we were powerless over alcohol—that our lives had become unmanageable.
2. Came to believe that a Power greater than ourselves could restore us to sanity.
3. Made a decision to turn our will and our lives over to the care of God as we understood Him.
4. Made a searching and fearless moral inventory of ourselves.
5. Admitted to God, to ourselves and to another human being the exact nature of our wrongs.
6. Were entirely ready to have God remove all these defects of character.
7. Humbly asked Him to remove our shortcomings.
8. Made a list of all persons we had harmed, and became willing to make amends to them all.
9. Made direct amends to such people wherever possible, except when to do so would injure them or others.
10. Continued to take personal inventory and when we were wrong promptly admitted it.
11. Sought through prayer and meditation to improve our conscious contact with God, as we understood Him, praying only for knowledge of His will for us and the power to carry that out.
12. Having had a spiritual awakening as the result of these Steps, we tried to carry this message to alcoholics, and to practice these principles in all our affairs.

## ALTMAIER, ELIZABETH M. (1952– )

---

Elizabeth Mitchell Altmaier, a native New Yorker, was born in 1952 to a father who was an engineer and a mother who was a homemaker. Unlike her brothers, for whom working careers were simply an expected eventuality, Altmaier was encouraged by the urgings she received during her educational experiences to explore her potential as a student and professional and to do so beyond the limited traditional venues open to women at that time—teaching and nursing.

Ironically, Altmaier came, quite literally, by way of chance to a career in psychology, selecting this area of study at random from a list of possible majors she found interesting. During her collegiate years, she found a fine match with the faculty in the psychology department at Wheaton College, and her mentor there persuaded her to pursue graduate studies in psychology. After collecting her B.A. in 1973 with honors from Wheaton College, she went on to earn a Ph.D. in 1977 in counseling psychology from Ohio State University.

It was at OSU that Altmaier found her feet as a scholar and developed her preference to view her research and professional efforts in an unfettered manner, away from what would be considered by others as “traditional” areas for interest and work in counseling psychology. This willingness to venture off the beaten path proved to be an important doorway for her in eventually pursuing her now well-established interest in health psychology (again, broadly defined). Following her clinical internship at the OSU Counseling and Consultation Service, she accepted her first academic post at the University of Florida in 1977. From there she moved, in 1980, to the University of Iowa where she is today.

Altmaier is truly a pioneer in counseling psychology; she was among the first to fully explore the potential avenues for research and applied education and training efforts in various areas of health psychology and its interface with medicine. Her initial, highly successful work in anxiety management for oncology patients receiving chemotherapy blossomed and extended over the years into National Institutes of Health (NIH)–funded research on coping strategies for stress and pain management with various oncology patient populations. Altmaier also made significant contributions to the research literature and medical care practices concerning patients who suffer from chronic low back pain. Finally, she has made a highly successful foray into helping medical school admission committees and training sites assess the suitability and potential success of applicants to their programs and has helped to improve the quality of physician–patient interactions in medical practice. In total, Altmaier has participated in more than \$1.5 million worth of grant-funded research efforts in these areas as well as in the general area of education and training in psychology. For this body of work, she received the 2003 Dorothy Booz Black Award for Outstanding Achievement in Health Psychology from Division 17 (Society of Counseling Psychology) of the American Psychological Association (APA).

For over 25 years, Altmaier has been a core faculty member in the APA-accredited program in counseling psychology at the University of Iowa. She also holds a secondary faculty appointment in the College of Public Health. She has enjoyed great favor and appreciation as a doctoral advisor to those fortunate students who have earned their doctoral degrees under her tutelage. Altmaier has held numerous administrative positions within the university, including department

chairperson, associate dean, and associate provost for faculty personnel and development. Illustrating her penchant for unique foci in her work, Altmaier has also been involved with the National Collegiate Athletic Association (NCAA), serving at the national level as a member of the Academics, Eligibility and Compliance Cabinet and the Study Group for the Use of Athletes' Names and Likenesses and at the local level on the University of Iowa's NCAA Certification Committee. Altmaier also serves on several other committees at the University of Iowa; she is its Big 10 and NCAA faculty athletics representative and is a member of its Board of Control of Athletics, its Presidential Committee on Athletics, and its Athletics Advisory Council. Finally, she has served on the search committees for several key sports administration positions at the University of Iowa, including the director of athletics, head coach for men's basketball, and head coach for football. In 2005, Altmaier was awarded the Michael J. Brody Award by the Faculty Senate at Iowa for her tireless contributions and service to the university.

Altmaier has also served the general psychology community in many capacities. For the APA, she chaired the Committee on Accreditation (ushering in the fully reformed accreditation standards and procedures in use today), was a member of the Commission for the Recognition of Specialties and Proficiencies in Professional Psychology, and served as a panel consultant for the Initiative on Women in Science and Technology. She has also served in governance roles for the Society of Counseling Psychology and the Council of Counseling Psychology Training Programs (CCPTP). Locally, she is a licensed psychologist in the state of Iowa and has served as chair of the Iowa Psychological Association's Ethics Board.

As a scholar, Altmaier's productivity is impressive; she has produced over 200 works to date, including 6 books, 14 book chapters, over 90 refereed articles, and over 80 research presentations. She has served in several editorial roles, including tours as editor of APA's *Clinician's Research Digest* and as associate editor of *The Counseling Psychologist*, *Journal of Counseling Psychology*, and *Contemporary Psychology*. Altmaier's efforts and accomplishments as a scientist have been nationally recognized. She is a fellow of the American Psychological Association and a charter fellow of the American Psychological Society (now the Association of Psychological Science), and she was the 1994 recipient of the American Psychological Association's prestigious Award for Distinguished Contribution to Education and Training in Psychology.

Most important and admirable given all she has accomplished, Altmaier has always been, and remains, very dedicated to her family—her husband Michael, her daughter Kathryn, and her son Greg. Those who have the good fortune to know Altmaier personally are aware of how much she enjoys her family and the experiences they share.

In reviewing her own career, Altmaier wrote, "In reflecting on the roads taken to date, and considering roads ahead . . . for me, uncommon choices . . . had in common a sense of excitement and the opportunity to work with others in a collaborative way. I look forward to more of these roads ahead" (1998, p. 103). Those who have had the good fortune to work with Altmaier have greatly appreciated her excitement, her willingness to collaborate, and the opportunity to share the road with her.

## AMERICANS WITH DISABILITIES ACT

---

The Americans with Disabilities Act (ADA), a landmark piece of civil rights legislation, is a product of

bipartisan support. Signed into law on July 26, 1990, the ADA “signals the end to the unjustified segregation and exclusion of persons with disabilities from the mainstream of American life,” declared President George H. W. Bush. Although the passage of the ADA was challenged by some legislators who considered its supporters a “sodomy lobby,” the legislation’s history demonstrates an unwavering commitment of the Congress to the more than 43 million people with disabilities in the United States. The ADA protects those who encounter various forms of discrimination, exclusion, and segregation because of their disabilities and gives them “the right to participate in the cultural, economic, educational, political and social mainstream,” said Senators Bob Dole and Tom Harkin in celebration of the ADA’s tenth anniversary.

The language in the ADA and in subsequent judicial decisions defines what the law covers and to whom the law applies. As psychologists increasingly are called upon to conduct disability evaluations for insurance compensation, academic accommodations, work modifications, and federal income subsidies, it has become critical for psychologists to understand how and the extent to which the ADA applies to specific service populations. Key language and concepts in the ADA are fundamental to standards and requirements for many disability evaluations. This entry provides an overview of the ADA and its legislative background along with a discussion of the statutory definition of the term *disability* and the reasonable accommodations and modifications mandated by the ADA.

### **Overview of the ADA and Legislative Background**

The ADA came from the civil rights movement of the 1960s and 1970s. It was modeled after the Civil Rights Act of 1964, which prohibits racial discrimination for employment and in public accommodations (e.g., hotels or restaurants). Different from the Civil Rights Act of 1964, where protection applies to people of all races, the ADA provides protection against discrimination only for those whose limitations meet the statutory definition of disability. The ADA also borrows several key definitions from an early disability rights statute, the Rehabilitation Act of 1973. These include definitions for *disability*, *reasonable accommodation*, and *undue hardship*.

In spite of their similarities, there are major differences between the Rehabilitation Act of 1973 and the ADA. Although both statutes are disability rights

laws, the Rehabilitation Act of 1973 applies only to programs or activities receiving federal financial assistance (e.g., education, courthouses, and transportation). The ADA, on the other hand, covers public or private employment, transportation, accommodations, and telecommunications regardless of whether federal funding is involved. Also, housing, education, and air transportation are issues included in the Rehabilitation Act of 1973 that were not covered by the ADA. It is clear from the legislative history that Congress made a great effort to make the ADA consistent with the Rehabilitation Act and did not intend it to supersede its statutory predecessor.

The ADA includes five separate titles. Title I involves employment issues. It prohibits discrimination with regard to job application procedures, hiring, advancement, discharge of employees, compensation, job training, and employment privileges. Title II involves public services. Any state or local government instrumentalities, the National Railroad Passenger Corporation, and commuter authorities cannot deny people with disabilities services or participation in programs or activities available to those without disabilities. Title III concerns public accommodations (e.g., roads and sidewalks) and services operated by private entities (e.g., movie theaters and amusement parks). All such accommodations that are newly constructed must be accessible to people with disabilities. For existing facilities, architectural barriers to services must be removed if modifications are readily achievable. Title IV concerns telecommunications. Telephone relay services must be provided by telecommunication companies for people who use telecommunication devices for the deaf or other similar devices. Title V involves miscellaneous provisions that prohibit coercing, threatening, or retaliating against individuals with disabilities or those attempting to assist individuals with disabilities to assert their rights.

### **Definition of a Disability**

One key issue that raised a substantial amount of discussion during the legislative history and after the passage of the ADA concerned the definition of disability. The definition in the ADA is similar to that of the Rehabilitation Act of 1973; *disability* means (a) a physical or mental impairment that substantially limits one or more of the major life activities of such individual, (b) a record of such an impairment, or (c) being regarded as having such an impairment.

The ADA expanded its protection not only to those currently with a disability or those with a documented record of one but also to those who are perceived falsely as having a disability. For example, a person with epilepsy might be treated adversely by his employer, because his employer believes his condition could limit his ability to perform his job. Although his condition is well managed and does not affect his job functions, this person still would be covered by the ADA.

### **Physical and Mental Impairment**

A physical or mental impairment means (a) any physiological disorder or condition, cosmetic disfigurement, or anatomical loss affecting one or more of the following body systems: neurological, musculoskeletal, special sense organs, respiratory (including speech organs), cardiovascular, reproductive, digestive, genitourinary, hemic and lymphatic, skin, and endocrine; or (b) any mental or psychological disorder, such as mental retardation, organic brain syndrome, emotional or mental illness, and specific learning disabilities.

While ADA covers a broad range of disabilities, including psychiatric conditions, health conditions, sensory impairments, orthopedic impairments, and learning disabilities, there are certain conditions to which ADA does not apply. Transvestites, transsexuals, bisexuals, gay identified individuals, and individuals with pedophilia, exhibitionism, voyeurism, gender identity disorders not resulting from physical impairment, other sexual behavior disorders, pyromania, compulsive gambling, kleptomania, and alcohol or drug addiction do not qualify individuals for ADA protection if they are treated adversely solely on the basis of these conditions.

In *Shafer v. Preston Memorial Hospital Co.*, Deborah Shafer, a nurse anesthetist, sued Preston Memorial Hospital under the ADA, claiming that Preston Memorial Hospital discriminated against her on the basis of her drug addiction. Shafer was addicted to fentanyl, a Schedule II narcotic analgesic, and had diverted postoperative fentanyl for her personal use. On the day of her completion of inpatient rehabilitation treatment, Shafer was notified by the hospital that her employment was terminated. Shafer sued Preston Memorial Hospital for employment discrimination and appealed the district court's order, which granted

summary judgment for Preston Memorial Hospital. The circuit court concluded that Shafer was a current user of an illegal drug and was therefore not considered disabled under the ADA. Because of her addiction, she was not considered "otherwise qualified" under the ADA, and therefore the hospital was not held liable for discharging her from her employment.

### **Otherwise Qualified**

The ADA protects the rights of those who are able to demonstrate that they are qualified individuals with disabilities. A "qualified individual with a disability" as applied to employment under the ADA is a person "who, with or without reasonable accommodation, can perform the essential functions of the employment position that such individual holds or desires." Essential job functions may be determined by the employer's judgment, written job descriptions, the amount of time the person has spent performing those functions, terms of collective bargaining agreements, work experiences of previous incumbents, and experiences of current incumbents in similar positions. For example, an employer may require all secretaries to have the ability to type 75 words per minute. A person with paraplegia who applies to be a secretary but fails to meet the typing requirement is not be considered a qualified individual with a disability as long as this employer can demonstrate that this particular requirement is an essential job function and that no reasonable accommodation can be provided to modify this requirement.

In education settings, a person with a disability must be able to fulfill the essential requirements of the program, with or without the provision of reasonable accommodations. Sherrie Lynn Zukle was a medical student at Davis School of Medicine at the University of California. After receiving unsatisfactory performance reports for several semesters, Zukle was placed on academic probation and referred for an evaluation, through which Zukle was found to suffer a learning disability. She consequently received academic accommodations, including extra time on exams and note-taking assistance. Zukle's subsequent academic and clinical performances remained poor in spite of her academic accommodations. She failed a clinical clerkship when she was placed on academic probation the second time and later was dismissed from the medical school. Zukle brought suit against the Regents of the University of

California, claiming that she experienced educational discrimination because of her learning disability. In *Zukle v. Regents of the University of California*, the circuit court argued that Zukle continued to demonstrate unsatisfactory performance after she was granted academic accommodations. The court ruled that Zukle failed to meet the school's academic standards, and her dismissal was justified. This case clarifies that accommodations do not give students with disabilities a competitive advantage over other students. Students with disabilities have to meet the same academic standards and requirements as students without disabilities.

### **Major Life Activities**

The ADA defines major life activities as including, but not limited to, caring for oneself, performing manual tasks, seeing, hearing, speaking, breathing, learning, walking, working, standing, sitting, and reading. A person who suffers traumatic brain injury and has difficulty with walking, memory, attention, or caring for his or her basic needs as a result would be considered a person with disability under the ADA. For example, in *Pacourek v. Inland Steel Co.*, the plaintiff was terminated from her job because of her absences on several occasions for infertility treatment. The court determined that reproduction was a major life activity and the plaintiff was therefore covered by the ADA.

### **Substantial Limitations**

A person is substantially limited when this person is "unable to perform a major life activity that an average person in the general population can perform" or is "significantly restricted as to the condition, manner or duration under which an individual can perform a particular major life activity" as compared to the average person in the general population. For example, Casey Martin, a professional golfer, suffered a rare circulatory disorder that resulted in the malformation of his right leg and blockage of his blood flow back to his heart. His illness made walking difficult and had the potential to lead to amputation of his leg. The Professional Golf Association (PGA) insisted that walking was part of the competition on its tour, and it refused to allow Martin to use a golf cart at certain tournaments. In *PGA Tour, Inc. v. Martin*, Martin

successfully invoked the protection of the ADA, arguing that he had a life-threatening health condition that prevented him from walking, and that the PGA should permit him to use a golf cart in order for him to compete professionally.

### **Mitigating Measures**

Reviewing court cases involving the ADA, judicial decisions have restricted the definition of disability when considering the impact of mitigating measures on a person's disability. For example, in *Sutton v. United Air Lines, Inc.*, twin sisters sued United Air Lines for failure to consider them for employment as airline pilots. Both of them suffered poor vision and could not pass the required vision test without glasses. They brought suit under the ADA, claiming that their poor vision had resulted in the refusal of employment. The Supreme Court ruled that the plaintiffs should be considered when their vision was in the corrected state. Because the plaintiffs' corrected vision was 20/20, the plaintiffs were not considered disabled, and therefore excluded from coverage under the ADA. In *Murphy v. United Parcel Service, Inc.*, the Supreme Court also ruled that mitigating measures should be taken into consideration in determining a person's disability. Vaughn Murphy had a blood pressure of 186/124, but, when he was properly medicated, Murphy's blood pressure was within healthy limits. Murphy was fired from his job because he failed to satisfy the health requirement of the Department of Transportation. The Supreme Court ruled that Murphy's hypertension was not a disability, because, according to the testimony of his physician, Murphy, when under medication, could function normally. In both cases, mitigating measures were used to determine whether a person is disabled or not. Because the plaintiffs were ruled not disabled, they were excluded from ADA coverage.

Although a person may not be considered disabled when mitigating measures are considered, some mitigating measures could be disabling and could contribute to a person's disability. For example, negative side effects of psychiatric medication could generate adverse symptoms that may cause additional impairments. Whereas the existence of a disability does not warrant ADA protection unless it causes substantial limits to major life activities, the use of mitigating measures does not automatically exclude a person

from coverage under the ADA. Substantial limits to major life activities have to be analyzed on a case-by-case basis.

### Reasonable Accommodations and Modifications

The ADA includes reasonable accommodations or modifications as part of the nondiscrimination mandate. Reasonable accommodations are changes in the work or education environment or in the way things are customarily done that would enable a qualified individual with a disability to enjoy educational and employment opportunities equal to those of individuals without disabilities. Reasonable accommodations should be provided without altering the essential components of the academic or job requirements. In classroom settings, reasonable accommodations may include modifications to the delivery methods of instruction (e.g., captioning of a class lecture vs. oral presentation), modifications to examinations (e.g., extended testing time), or flexibility in attendance policies. In cases of employment, reasonable accommodations may include, for example, modifications to a work schedule, changes in ways work is performed, use of communicative devices (e.g., teletypewriters), or modifications to the work environment.

Concerning modifications to the work environment, both Title I and Title III of the ADA include statutory language that prohibits discrimination resulting from structural barriers. Title I of the ADA prohibits discrimination at the employment facility, whereas Title III of the ADA applies to public accommodations and services. The ADA requires that facilities built after January 26, 1993, be accessible and that modifications to existing public accommodations made after that date also be accessible. Alternative methods of providing services to the public are to be implemented where structural removal of barriers is not “easily achievable” because of difficulty or expense.

Accessibility requirements for public accommodations are outlined in the ADA Accessibility Guidelines for Buildings and Facilities (ADAAG). The ADAAG is issued by the United States Architectural and Transportation Barriers Compliance Board (or Access Board), which was formed to help to establish accessibility standards for new and existing facilities. The guidelines were revised in July 2004 to maintain consistency with technology and national standards, and they are used routinely by architects. Examples of

ADAAG guidelines include the number of locations for wheelchairs at any given seating capacity, height and clearance of lavatories, signage, and visual alarms.

There are other disability rights statutes that interrelate, to various degrees, with the ADA. In addition to the Rehabilitation Act of 1973, there are, for example, the Individuals with Disabilities Education Improvement Act of 2004 (IDEIA), which applies to education rights of individuals with disabilities at elementary and secondary levels; the Family and Medical Leave Act (FMLA), which applies to employees’ rights to care for family members’ medical conditions; and the Fair Housing Act, which prohibits discrimination by the direct providers of housing against individuals because of their race, disability, religion, sex, national origin, or familial status.

## ART THERAPY

---

Art therapy combines the process of art making (drawing, painting, sculpture, and other art media) with methods of psychotherapy to improve and enhance the psychological well-being of individuals of all ages. It is based on the belief that the creative process involved in artistic self-expression helps people to resolve psychological problems, develop interpersonal skills, manage behavior, reduce stress, increase self-esteem and self-awareness, and achieve insight. Individuals who are referred for art therapy need not have previous experience or skill in art, because art therapy is not primarily concerned with formulating an aesthetic or diagnostic assessment of the people's images. The overall goal of art therapy is to enable clients to achieve emotional, interpersonal, or cognitive growth through specific art-making experiences.

While visual expression has been used for healing throughout history, it was not until the early 20th century that psychiatrists became interested in the artwork created by their patients with mental illness and in how these patients used art expression as a form of communication. At around the same time, educators discovered that children's drawings and paintings reflected developmental, emotional, and cognitive growth and that children's art and play provided a means of evaluating psychological disorders. By the 1940s, art therapy emerged as a distinct discipline, and hospitals, clinics, and rehabilitation centers increasingly began to include art therapy programs along with traditional talk therapies or as "milieu therapies." Subsequently, the profession of art therapy grew into an effective and important method of assessment and treatment with children, adults, and families as recognition increased that the creative process of art making enhanced recovery, health, and wellness.

As with other forms of psychotherapy, the relationship between the art therapist and the client is a key component of treatment. However, art therapy differs from other forms of psychotherapies because, in addition to talking, art is also used as a form of communication; art also serves as an intervention. In essence, there are several aspects of art therapy that set it apart from other forms of psychotherapy: (1) It helps individuals to externalize feelings and thoughts in a unique and tangible way; (2) it helps individuals to convey feelings or thoughts that may be difficult to verbalize; and (3) it is usually perceived as

nonthreatening, neutral, or even as "play," reducing resistance to treatment.

Art therapy is used to assess and treat anxiety, depression, and other mental and emotional problems and disorders; substance abuse and other addictions; family and relationship issues; abuse and domestic violence; social and emotional difficulties related to disability and illness; trauma and loss; physical, cognitive, and neurological problems; and psychosocial difficulties related to medical illness. Art therapy programs are found in a number of settings, including hospitals, clinics, public and community agencies, wellness centers, educational institutions, businesses, and private practices. Methods of art therapy are often combined with other forms of creative arts therapies or expressive therapies such as music, dance and movement, drama, or play therapies as well as numerous forms of psychotherapy such as psychoanalytic, person-centered, humanistic, cognitive-behavioral, narrative, and solution-focused approaches.

## ASPERGER'S SYNDROME

---

*See* AUTISM/ASPERGER'S SYNDROME

---

## ATTENTION DEFICIT/ HYPERACTIVITY DISORDER

---

Attention deficit/hyperactivity disorder (AD/HD) is the most common childhood behavior disorder. It is characterized by developmentally elevated levels of

inattention, impulsivity, and hyperactivity. These three symptoms are so imperative that they have been referred to as the “holy trinity” of AD/HD. Over the years, the disorder has gone by a number of different names, including minimal brain dysfunction (MBD), hyperkinesis, hyperkinetic reaction of childhood, and attention deficit disorder (ADD). Regardless of the name, some variation of those three symptoms has been included as a part of the diagnosis. Concerns related to symptoms of AD/HD represent 30% to 40% of all psychologically based referrals made to primary care medical practices.

In the past, it was widely assumed that children outgrew AD/HD during their adolescent or early adult years. While some individuals do appear to no longer be affected by the disorder once they reach their early 20s, there is increasing evidence that 40% to 60% of children will continue to experience debilitating symptoms of AD/HD well into adulthood.

Attention deficit/hyperactivity disorder negatively affects not only the affected individual, but also those around him or her. Consequently the assessment and treatment of AD/HD needs to be comprehensive and systemic. Research suggests that pharmacological and behavioral treatments are quite effective in reducing the severity of the symptoms and resulting negative effects. In addition, individuals receiving treatment are less likely to develop additional psychiatric disorders as they get older.

## Prevalence

While there is variability in the estimated prevalence of the disorder, most researchers agree that AD/HD affects between 3% and 7% of the school-age population. The reported prevalence differences likely reflect variations in assessment methodologies, such as sampling procedures, assessment instruments, and diagnostic criteria. For example, the estimates of affected children tend to be inflated when sampling procedures do not assess for the degree of functional impairment. There is currently limited information regarding the prevalence of AD/HD in adults, but based upon extrapolations from childhood estimates, some researchers have suggested that AD/HD affects between 2% and 6% of the adult population.

Prevalence variation also appears to be related to gender. There is a large body of empirical evidence to suggest that males are much more likely to be diagnosed with AD/HD than females. Estimated male-to-female ratios for the disorder range from 2:1 to 9:1

depending upon the setting (community sample vs. clinic referred sample). It also appears that the gender discrepancy is lower for individuals with the predominantly inattentive subtype of AD/HD.

## Diagnostic Criteria

The *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)* specifies 18 symptoms that compose the disorder. Nine of the criteria are related to symptoms of inattention, and nine are related to symptoms of hyperactivity/impulsivity. Symptoms of inattention include failure to pay attention, having difficulty with sustained attention, not listening, not following through on instructions, poor organization skills, avoiding tasks requiring sustained mental effort, often losing things, being easily distracted, and being forgetful. Symptoms of hyperactivity include fidgeting often, getting out of one's seat at inappropriate times, behaving or feeling restless, not being able to play quietly, being compelled to be active, and talking excessively. Symptoms of impulsivity include blurting out answers, having difficulty awaiting one's turn, and interrupting others.

Based upon this cluster of symptoms, three primary subtypes of AD/HD can be diagnosed. If an individual exhibits six of the nine inattention symptoms for a period of at least 6 months, and if these exhibitions are both maladaptive and inconsistent with the individual's developmental level, the diagnosis of *attention deficit/hyperactivity disorder, predominately inattentive type* can be made. If an individual exhibits six of the nine hyperactivity/impulsivity symptoms for at least 6 months and to a maladaptive degree given the individual's developmental level, the diagnosis of *attention deficit/hyperactivity disorder, predominately hyperactive-impulsive type* can be made. If an individual exhibits significant elevations on six of the inattention symptoms and six of the hyperactive-impulsive symptoms, he or she could be diagnosed with *attention deficit/hyperactivity disorder, combined type*. In all of the subtypes of AD/HD listed above, some symptoms causing impairment must have been present before the age of 7, some impairment from symptoms needs to be present in two or more settings, and there needs to be clear evidence of significant impairment in social, academic, or occupational functioning. In cases where it is unclear if these criteria have been met, a diagnosis of *attention-deficit/hyperactivity disorder, not otherwise specified* could be made.

The final criterion to consider is that the symptoms could not be better accounted for by another mental disorder. This is a very important criterion to consider. Symptoms characterized by inattention, impulsivity, and hyperactivity can occur in numerous other mental disorders. The clinician needs to consider not only that the individual has some disorder *other than* AD/HD, but that the individual has another disorder *in addition to* AD/HD.

### Making the Diagnosis

When making the diagnosis of AD/HD, the clinician has a number of different tools to choose from. First are the *DSM-IV* AD/HD rating scales. These scales take the *DSM-IV* criteria and have parents or teachers rate a child's behavior on a Likert-type scale. These specific scales tend to be relatively brief and easy to administer and have adequate psychometric properties.

The second type of assessment instrument is the broad-band rating. These instruments assess for a broader array of behaviors than just those associated with AD/HD. Examples of commercially available instruments that would fall into this category include the Child Behavior Checklist (CBCL) and the Behavior Assessment System for Children–2nd Edition (BASC-2). Both of these instruments assess for a broader range of symptoms, including depression, aggression, and somatic complaints. These instruments are well normed, have acceptable psychometric properties, and are available in parent, teacher, and self-report versions. Research suggests that youth self-report versions are rather poor at differentiating between children with AD/HD and controls, suggesting that children may not be accurate informants of their behavior problems. In addition studies suggest that when there are discrepancies between parents' and teachers' perceptions on such instruments, teachers tend to be the more accurate informants. The reason for this is that teachers usually have a better understanding of child development and age-appropriate behavior than many parents do.

Structured and semistructured interviews are a third type of assessment tool that can be employed when making a diagnosis for AD/HD. These instruments have advantages over rating scales in that the clinician can follow up on parent ratings and ensure that the parent understands the intent of the question. However, interviews are time intensive for both the examiner and the informant (usually the parent). The Diagnostic

Interview for Children and Adolescents–Revised (DICA–R) and the Diagnostic Interview Schedule for Children–Version IV (DISC–IV) are two of the more widely used diagnostic interviews that have adequate psychometric properties.

Impairment rating scales are a fourth category of assessment for AD/HD. Some measures provide documentation for global or overall impaired psychosocial functioning (e.g., the Children's Global Assessment of Functioning), whereas others provide a multidimensional rating of impairment (e.g., the Child and Adolescent Functional Assessment Scale). Some of the more widely used impairment rating scales show good temporal stability and interrater reliability. In addition they also have evidence for convergent and concurrent validity.

A fifth category of assessment is observational measures. There is a long tradition of conducting observations for children with behavior disorders. Observations can occur in analogue or naturalistic settings. Observation measures can be very complex and assess multiple behaviors across multiple settings or can be relatively simple and involve the assessment of only a couple of behaviors (e.g., verbal intrusions and out-of-seat activity in the classroom). Studies have shown that when the behaviors for observation are carefully chosen, observation measures that involve relatively few behaviors can be as effective as the more comprehensive systems.

Physiological or laboratory measures form a final category of assessment. While no such measures can diagnose AD/HD, some are widely used to aid in making the diagnosis. One group of such measures is the continuous performance tests (CPTs). There are many different types of CPTs available; some of the more common commercially available ones include the Test of Variables of Attention (TOVA), Conner's CPT, and the Individual Variables of Attention (IVA). All CPTs attempt to provide a computerized assessment of inattention, response inhibition (hyperactivity), and reaction time (impulsivity). While studies have shown that individuals with AD/HD do perform more poorly on these tests than do controls, individuals in other clinical groups (e.g., learning disabilities, depressed) also perform more poorly than controls.

Some researchers have argued that when assessing for AD/HD, less emphasis should be placed on identifying symptoms that confirm the diagnosis and more emphasis should be placed on evaluating the function of the behavior that is causing the problems. Through

functional behavioral analysis, clinicians are better equipped not only to recognize the maladaptive behaviors but also to implement a strategy to treat them.

### **Associated Features**

When compared to children of similar age and gender, children with AD/HD experience functional and adaptive impairment academically, behaviorally, and socially. The core symptoms of inattention, impulsivity, and hyperactivity can manifest in various ways. Attention is frequently defined by a set of observable behavioral characteristics. For example, children with AD/HD may find it difficult to remain focused on an assignment with ongoing distractions. Each passing moment may present a challenge for them to focus on a particular stimulus. Furthermore, once distracted, these children are often slower to return to task. Factors such as background noises, their own thoughts, and activity of any kind present potential distractions, which may preclude the child from staying on task. Adults working with these children frequently report that the children appear to be daydreaming, lethargic, or prone to not listening to instructions.

Impulsivity represents the inhibitory deficits an individual exhibits. These problems are associated with the tendency to interrupt others, to call out answers before the speaker can finish a question, and to have trouble waiting one's turn. Frequently, children with AD/HD report acting without considering the consequences for their behavior. Problems with low frustration tolerance and temper outbursts may be related to impulsivity. Some researchers, such as Russell Barkley, consider impaired inhibition to be the paramount symptom associated with AD/HD.

Hyperactivity is the third component of the AD/HD triad. When compared to normal controls, children with AD/HD are significantly more active. Often this activity appears aimless, as if the child is compelled to be doing something. This tendency may also result in the child engaging in more high-risk behaviors, such as running into the street without looking or jumping from a fast-moving object. These risk-taking behaviors appear to persist in adulthood. Adults with AD/HD have been found to be more prone than controls to substance abuse, traffic accidents, and legal problems.

Frequently, a child with AD/HD will first exhibit problematic behavior at school. Teacher-student relationships are often marked by strain and significant

discord. Children with AD/HD frequently engage in disruptive behavior, refuse to follow directions, and fail to complete assignments. Observers often misinterpret such a child's dislike for tasks that require sustained attention as an indication that the child is lazy or immature. Additionally, when compared to peers, children with AD/HD tend to lose necessary materials and have more organizational difficulties. Consequently parents and teacher may view them as being oppositional and defiant. These behaviors often result in increased disciplinary referrals, lower academic achievement, and more school failure.

Parents of children with AD/HD frequently experience problems relative to parenting practices, parent-child interactions, and parenting stress. They frequently exhibit higher levels of stress than parents of controls. In addition, there is a greater chance of disagreement between parents relative to child-rearing practices. Mothers of children with AD/HD are more likely to be depressed, and fathers are more likely to have substance abuse problems, than parents of controls.

Parent-child interactions are frequently marked by conflict. Research suggests that these parents are more likely to engage in punitive parenting practices. Perhaps in response to these conflicted interactions, children with AD/HD become even more overactive, defiant, uncooperative, and impulsive. This further exacerbates the parent-child conflicts. There is some research to suggest that the use of harsh physical discipline is associated with the development of oppositional defiant disorder or a conduct disorder in children with AD/HD. Older adolescents and young adults who received harsh physical punishment as children appear to be more impaired than their AD/HD peers whose parents did not use such practices.

In addition to negative family interactions, peer relationships also tend to suffer. Children with AD/HD interact less with playmates during conversation, tend to be more bossy, exhibit a diminished receptivity to social cues, and appear less likely to engage in close friendships. The aforementioned problems are exacerbated when there is a comorbid oppositional defiant or conduct disorder.

Low self-esteem has been observed more frequently in children with AD/HD than in controls. In an effort to preserve their self-esteem, children with AD/HD may overestimate their performance in the domains with greatest deficits. So, a child with AD/HD who is

struggling in school may exaggerate his or her academic achievement for the purpose of self-protection.

### Comorbid Disorders

When a child has AD/HD, he or she is more likely than not to have a comorbid disorder. Recent research suggests that up to 87% of children with AD/HD have at least one comorbid condition and up to 67% have at least two. Approximately half of children with AD/HD will go on to develop another behavior disorder such as oppositional defiant disorder or conduct disorder. Other common comorbid conditions include the following: learning disability (40% to 60%), depressive disorder (17% to 30%), anxiety disorder (20% to 43%) and substance abuse disorder (18% to 36%). There is some evidence to suggest children with AD/HD may be more likely to develop juvenile-onset bipolar affective disorder. While half of the individuals with Tourette's syndrome have AD/HD, children with AD/HD do not appear to be more likely to develop Tourette's.

### Etiology

There are numerous hypotheses relative to the etiology of AD/HD. However, few are supported with empirical research. One of the theories that has some support surmises a strong biological component. The evidence for a genetic influence in AD/HD has been gathered from family studies, twin studies, and molecular genetics studies. From the research relative to families, there are data that suggest that parents with an AD/HD diagnosis are more likely than non-AD/HD parents to have children with the same disorder. In fact, some researchers assert that there is a 57% chance that parents with AD/HD will have children with the same diagnosis.

Researchers have also looked at the prevalence of the disorder in parents of children who have been diagnosed with AD/HD. These studies found that 15% to 20% of the mothers and 20% to 30% of the fathers of an affected child also have AD/HD. There is also a 1 in 3 chance that a child with AD/HD will have a sibling who also has the disorder. Identical twins also appear to have increased risk for AD/HD. However, with these studies it is difficult to tease out environmental contributions to the expression of the disorder. Gonzales-Limas suggested that 70% to 95% of the trait variability among individuals with AD/HD can

be accounted for with genetic heritability. Researchers involved in molecular genetics research believe that several genes are related to risk for AD/HD. These genes include DAT1, DRD4, and DHB.

Some studies have found that birth complications may increase the likelihood that a child will develop AD/HD. In addition, several studies suggest a link between premature birth or low birth weight and AD/HD. In fact, it has been estimated that low birth weight is associated with 14% of all AD/HD diagnoses. Maternal behaviors such as smoking and using drugs or alcohol during pregnancy have also been linked to low birth weight and increased risk for AD/HD.

Several environmental variables have been consistently implicated in the expression of AD/HD. Correlations between exposure to environmental toxins, such as lead, and hyperactive behaviors have been reported in numerous studies. Other environmental variables may include malnutrition, disease, and trauma. Several large, well-controlled studies that systematically evaluated the diets of children for the effects of additives such as processed sugar, wheat germ, and food dyes on the development and expression of AD/HD have failed to find significant differences between groups of children who were exposed to the additives and those who were not.

### Psychopharmacological Treatments

Stimulant medications are one of the most widely used and oldest treatments for AD/HD. In fact, stimulants have been used to treat AD/HD since the mid-1930s. The therapeutic mechanism of action relative to stimulant medications is not precisely understood. Data generated from a large body of research suggest that stimulants increase neural activity in some parts of the brain; in others areas stimulants actually inhibit neural activity. Stimulant medications have been shown to be effective at increasing an individual's ability to focus attention and to inhibit impulsivity. It has been estimated that up to 82% of children over the age of 5 with AD/HD have a positive response to stimulant medication. However, a growing body of research suggests that persons who do not respond to standard stimulant medication may respond positively to low doses of amphetamines.

The use of stimulant medications does come with negative side effects, including loss of appetite and difficulty sleeping. In addition, the benefits from stimulants

may be relatively short-term. Some have estimated that stimulants lose their effectiveness within 5 years. Given the potential contraindications and limited longevity of psychotropic interventions, prescriptions must be issued judiciously. Physicians can usually adjust the doses of the medications to alleviate most side effects, and children frequently take “drug holidays” during the summer months to decrease the likelihood that a child will develop a tolerance to the medication. While stimulant medications have been shown to be effective in treating AD/HD, multiple studies have shown that optimal treatment effects result when individuals receive pharmacological intervention paired with behavioral interventions.

### Behavioral Interventions

Behaviorally based treatment plans are commonly used in clinics, schools, and day treatment centers to treat children with AD/HD. Numerous behavioral interventions exist; however only parent-training programs and classroom-based treatments have been supported by evidence-based research. Many behavioral interventions are based upon an antecedent, behavior, and consequence (A-B-C) paradigm. According to this theory, all behaviors (B) are preceded by environmental variables (A), and the positive or negative reactions children receive from that behavior (C) will determine whether a given behavior will increase, decrease, or remain unchanged. Behavior management programs that identify target behaviors and provide for the contingent application of positive or negative consequences is the most common manifestation of behavioral interventions. For adults with AD/HD, self-management procedures that involve self-monitoring, stimulus control, and self-reward are often used.

### Parent Training

Parent-training programs are a common, well-researched, and efficacious treatment for AD/HD. Some examples include Cunningham’s Community Parent Education (COPE), Eyberg’s Parent–Child Interaction Therapy (PCIT), and Barkley’s Parent Training Program. These parent-training programs have all been subject to research and are widely used. The methods and rationales associated with parent training programs are usually very similar: they endeavor to teach parents how to shape their child’s

behavior with appropriate behavioral management techniques.

The majority of parent-training programs include psychoeducational sessions. In these sessions, parents are provided with information about AD/HD (e.g., prognosis, course, and etiology). These sessions may be supplemented with handouts, books, or videotapes. Providing parents with information about AD/HD improves their perceptions of their children and may improve treatment outcomes.

In addition to the general overview of AD/HD, parents are also taught the basic principles of behavioral modification. Attending skills are also a critically important component of these programs. *Attending skills* refer to a process in which the parent listens, provides positive attention, and ignores mild undesirable behaviors exhibited by the child. Frequently these attending skills are practiced in a low-stress, play-based setting. Attending skills represent the cornerstone of behavioral modification; however, by themselves these skills will not effectively shape the target behaviors. Therefore, parent training focuses on several other aspects of parenting. Often parents are required to completely change the manner by which they interact with their children. This is because many parents appear to overfocus on undesirable behaviors and neglect to acknowledge when desirable behaviors occur. Parent training teaches parents to listen more effectively, shift the focus of attention from undesirable to desirable behavior, consider developmental variables, and issue frequent positive reinforcement.

The success or lack thereof associated with any parenting intervention is predicated upon the quality of the parent–child relationship. Parents are often encouraged to examine the quality of the relationship they have with their children and to identify conditions that negatively impact their relationship. Parents begin to explore the relationship between their children’s behavior problems and their own reactions when the children misbehave. For example, a parent may unintentionally reinforce an undesirable behavior; this often occurs when parents attend primarily to undesirable behavior and overutilize punishment. During this critically important phase, ineffective parenting practices are identified and replaced with more efficacious methods.

Skilled use of reinforcement is quintessential to successful behavioral change. There are several prerequisites to the implementation of a reinforcement system. First, the parent must identify, define, and

communicate behaviors in clear, specific, and measurable terms. Furthermore, whenever possible, the goals should be articulated with positive language and focus on the behavior that the child will exhibit, rather than what the child will cease to exhibit. A special type of reinforcement is praise. Parents learn that if they want to modify their child's behavior through praise, they should use *specific-labeled praise*. This means the parent makes sure that the child knows exactly why he or she is being praised. So instead of saying "You're a big boy," the parent learns to say, "You got up and got dressed all by yourself. Thank you for helping. You are such a big boy."

The second technique, punishment, must be implemented judiciously, and parents should always remember that reinforcement results in more enduring behavior change. In parent training (and behavior modification programs), a specific form of punishment called *response cost* is also used to shape behavior. Response cost refers to the removal of some privilege when the child exhibits an unwanted behavior. So, a child may lose his or her video game privileges for the evening if he or she chooses to neglect the dishes. Again, it is critically important that parents implement punishment strategies with caution. Unfortunately if parents want to stop a behavior quickly, the use of punishment is the fastest way to do so, but that change tends to be short-lived. Long-term behavior change occurs best with reinforcement.

Another effective behavioral intervention, *time-out*, is conceptually similar to response cost. While response cost results in the removal of a privilege, time-out results in the removal of positive reinforcement. Like response cost, time-outs should be utilized sparingly. Some researchers suggest that time-outs be limited to as few as two predetermined noncompliance behaviors. Similarly, the location and amount of time spent in time-out for a given offense should be predetermined. Children should be required to correct the behavior that actuated the time-out; in addition, the child should be rewarded for positive behavior. While a common rule of thumb for the length of time to keep a child in time-out is 1 minute for each year of age, research suggests that time-out achieves maximal impact for children in 3 to 5 minutes, regardless of their age.

The *token economy* represents another popular technique, which utilizes both reinforcement and response cost. As with the other techniques, the focus of the token economy should be on positive behavior.

A complete explanation of the token economy would exceed the scope of this entry, so only basic principles will be addressed.

Token economies are often used when the child requires frequent reinforcement. A list of target behaviors—following the guidelines relative to positive reinforcement—is generated. These behaviors should be clear, concrete, and measurable. Next, parents, teachers, or helping professionals issue tokens (usually plastic chips) or points (recorded in a notebook or calendar) when the child exhibits desirable behavior. The tokens or points are taken away when the child engages in undesirable behaviors. After a predetermined period of time, the child is allowed to exchange tokens or points for a privilege (e.g., extra time playing video games) or some other reinforcing product (e.g., comic book, candy bar).

## AUTISM/ASPERGER'S SYNDROME

---

According to the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)*, the formal diagnostic category for autism and Asperger's syndrome is pervasive developmental disorder, or PDD. Pervasive developmental disorders include autistic disorder, Rett's disorder, Asperger's disorder (syndrome), childhood disintegrative disorder, and pervasive developmental disorder—not otherwise specified (PDD-NOS). Mental health professionals, however, often refer to each of these disorders as autism spectrum disorders (ASD), which better conveys the continuum of

types and severity of symptoms delineated by this diagnostic label.

## The Autism Spectrum

The first accurate description of autistic symptoms appeared in 1943, when Leo Kanner published "Autistic Disturbances of Affective Contact." The term *autism*, a derivative of the Greek word *autos* or *self*, highlighted the primary symptom exhibited by the 11 children in Kanner's study. Kanner noted that these children presented with marked deficits in their ability to relate to other people.

Over time, the conceptualization of autism has evolved into the current view of a spectrum of psychological disorders identified by a fundamental deficit in one's ability to navigate the social world. Autistic disorder and Asperger's disorder, for example, share a common symptom in a significant impairment in social functioning relative to the individual's chronological age and measured intelligence.

The key distinguishing criteria for autistic disorder is a marked impairment in language, cognitive, or adaptive development before age 3. While some persons with autistic disorder are "high-functioning" (HFA), it is not uncommon for someone with autism to have severe language, emotional, and cognitive delays—including mental retardation. A classically autistic individual presents with early communication and language delays, cognitive deficits, stereotyped and restricted interests and behaviors, and a profound lack of social awareness. Stereotyped and restricted interests may include a specialized interest in a certain area or subject such as electrical wiring or computers. Stereotyped behaviors are often exhibited as repetitive hand, finger, or whole-body movements aimed at providing increased self-stimulation. These are referred to as self-stimulatory behaviors or "stimming" and should be distinguished from the motor tics that are typically observed in anxiety disorders.

A year after Kanner published his findings on autism, Hans Asperger, an Austrian pediatrician, published a paper discussing four boys who presented with symptoms similar to those described by Kanner. Asperger, however, described children that were higher-functioning in terms of developmental history than those described by Kanner.

Similar to autistic disorder, persons with Asperger's disorder present with social difficulties that pervade

their ability to establish and maintain peer relationships. Moreover, they exhibit highly specialized areas of interests and are often referred to as being “experts” on that subject. A person with Asperger’s disorder, however, is differentiated from a person with autism in that the individual does not have a history of significant cognitive, adaptive, or language delays.

While individuals with Asperger’s disorder do not have a history of communication delays, they, like persons with autistic disorder, present with peculiar linguistic tendencies, including a pedantic style, awkward tone and rate (often referred to as “robotic”), and difficulties maintaining reciprocal, give-and-take conversations. Moreover, they often avoid using idioms and figures of speech because they struggle to separate the literal meaning of these expressions from the underlying expressive connotation.

### **Etiology**

Researchers continue to struggle to identify specific causes of autism. Research strongly suggests, however, that autism may be a heritable disorder. With increased funding and support for autism research, scientists can continue to explore the genetic epidemiology of the disorder and other possible causes.

### **Diagnosis**

Autism spectrum disorders are formally diagnosed through a comprehensive psychological evaluation of the individual conducted by a qualified professional, such as a licensed psychologist. A thorough assessment should begin with a clinical interview that explores developmental history and current social, emotional, behavioral, and cognitive functioning. The clinician then administers standardized global assessment questionnaires that measure social, emotional, and cognitive functioning. Other standardized questionnaires and assessment tools that are specific to ASD are also administered, such as the *Autism Diagnostic Observation Schedule*. It is important to include a behavioral observation of the individual in an unstructured social setting.

### **Treatment**

Once a diagnosis is made, treatment recommendations can then be individualized to the individual’s

specific diagnosis and needs. Researchers agree, however, that early intervention for persons with ASD is essential and can significantly improve an individual’s level of functioning.

Current research indicates that lower-functioning individuals with autistic disorder benefit from intense behavioral therapy, such as applied behavioral analysis (ABA) and verbal behavior analysis (VB), to improve functional communication skills, adaptive skills, and behavior. ABA utilizes the principles of behavioral psychology and pairs repeated trials with a positive reinforcer to modify inappropriate behaviors by improving receptive language skills. VB also uses behavior modification techniques but emphasizes the functionality of expressive language skills. Another effective program, treatment, and education of autistic and communication handicapped children (TEACCH), uses an amalgamation of therapeutic techniques and methods to address the specific needs of each individual.

Persons with ASD often report significant problems relating to others and establishing peer relationships; thus a key component of treatment is an intensive focus aimed at improving the individual’s social skills. It is common for persons with ASD to present with social skills deficits, including difficulties establishing and maintaining reciprocal conversations, an inability to understand nonverbal social cues (e.g., facial expressions), problems communicating to others through nonverbal language (e.g., using appropriate eye contact to modulate a social interaction), and inadequately processing or a complete lack of awareness of others’ emotions. Thus, social skills training for AS focuses on topics ranging from conversational skills to personal space.

Although there are many techniques and programs designed for persons with ASD, there is no one-size-fits-all approach to treatment. Given the variability of symptoms and the frequency of comorbid disorders, it is common for clinicians to take a multidisciplinary approach in treating the disorder. Treatment teams might include licensed psychologists, occupational therapists, speech and language pathologists, medical professionals, teachers, and physical therapists.

### **Changes and Challenges**

The autism spectrum disorders continue to be a mental health issue of intense interest for clinicians, researchers, and politicians. Increased federal funds

for further research on autism and Asperger's disorder have led to an expansion of information and resources available to both parents and clinicians. Given the heterogeneity of ASD symptoms, a large portion of these funds are allocated to improving diagnostic procedures, such as refining current assessment tools and their ability to identify persons with ASD. Moreover, the importance of early and intensive intervention as well as effective treatment across the life span have continued to be the foci of research.

## BEHAVIORAL OBSERVATION METHODS, ASSESSMENT

---

Behavioral observation is a widely used method of behavioral assessment. Unlike other methods of behavioral assessment, most of which rely on people's perceptions of behavior, behavioral observation involves watching and recording the behavior of a person in typical environments (e.g., classrooms). The assumption is therefore that data collected are more objective than are perceptions. Most methods of behavioral observation provide quantitative and objective data that can be used to determine current levels of behavior, to set goals for behavioral improvement, and to measure change following intervention plans.

Depending on the nature of the behaviors of concern, observers may be interested in any one or a combination of several characteristics related to the behavior. The most common characteristic observed is frequency, or how often a behavior occurs. Other characteristics include magnitude (how intense a behavior is) and duration (how long a behavior lasts). A behavior change agent might be interested in reducing the frequency of a problem behavior, reducing its intensity, or reducing its duration. Regardless of which characteristic is observed, it is important to measure that characteristic consistently throughout the behavior intervention process.

### **Anecdotal (ABC) Recording**

One exception to the suggestion that behavioral observation methods produce objective and quantifiable information about behaviors is anecdotal recording. Anecdotal

recording involves recording and interpreting a narrative of behavior during an observation period using an antecedent-behavior-consequence (ABC) format for interpreting behavior. To conduct an anecdotal observation, an observer records all behaviors observed, along with what was observed to occur before and after the behaviors. For this type of observation, it is important that only observable behaviors are recorded. No inferences about behaviors should be made. For example, if a student is observed to slam her book closed, the observer should record "slammed book closed," rather than "student frustrated." Either during or after the observation period, it is helpful to arrange observations into a chart that specifies behaviors, antecedents (what happened prior to the behavior), or consequences (what happened as a result of the behavior). It is also helpful to keep track of the time at which behaviors were observed to occur.

Anecdotal recording is a method of choice when behaviors of concern are unclear. In other words, if one is unsure about the exact nature of a behavioral concern, anecdotal recording allows the observer to include observations of all behaviors. This is often a necessary first step in targeting particular behaviors for more focused or structured observation. Once behaviors of concern are pinpointed, however, the subjective and effuse nature of anecdotal recording makes it unsuited for continued use. At that point, the methods of choice are those that provide more quantitative and objective data. These methods are discussed below.

### **Interval Recording Methods**

Interval recording methods produce a record of the number of intervals during which a behavior is

observed to occur. There are three basic variations on interval recording—partial-interval recording, whole-interval recording, and momentary time sampling—but all focus on observing the frequency of the behavior, and all use simple *yes* or *no* counts of whether a behavior was observed to occur during each interval.

### ***Partial-Interval Recording***

Partial-interval recording begins with the observer determining the size of the interval needed. The size of the interval depends on the nature of the behavior, but 30 seconds is a common choice. Next, the observer creates a grid of boxes on a sheet of paper, with each box representing one interval. If the observation is conducted without the assistance of a computer program, a stopwatch is typically used to time the intervals. The observer begins observing the student or client for the presence of the target behavior. After the interval has passed, the observer records whether the behavior occurred during the interval. If observations are being recorded on paper, an X would be marked in the appropriate box if the behavior occurred. The observer then observes for the remaining intervals until the observation period is over.

Observers may choose one of two options for actually recording whether the behavior occurred during the interval. One option is to set aside a prespecified amount of time for the actual recording of the behavior. For example, if an interval is 30 seconds in length, the last 5 seconds of that interval might be devoted to recording. During those 5 seconds, no behavior that occurs is recorded. The second option is to observe and record simultaneously. In this option, behavior would be observed for the entire 30 seconds, and the observer records while continuing to observe. The advantage of the first option is that no behaviors are missed while recording. This is especially important if more than one behavior is being observed at the same time. The disadvantage, however, is that 5 seconds of each interval are unavailable for data collection. If only one behavior is being observed, if maximum observation time is desired, and if the observer is skilled in behavioral observation, the observe-and-record-simultaneously option may be preferred.

### ***Whole-Interval Recording***

Whole-interval recording is similar to partial-interval recording in all aspects but one. In partial-interval

recording, the behavior is recorded as having occurred (i.e., an X is placed in the box) if it was observed to occur at any point during the interval. For example, if head banging is the behavior of interest, it would be recorded as having occurred even if it lasted only 3 seconds. In whole interval recording, the behavior has to have occurred throughout the entire interval in order to be recorded as having occurred. Head banging in the previous example would only be marked as having occurred if it lasted for the entire 30-second interval.

Data interpretation is the same, regardless of whether one is using partial- or whole-interval recording. Once the observation period is over, the data collected are aggregated so they are easily understandable. This involves adding the number of intervals during which the behavior occurred, dividing the sum by the number of intervals observed, and multiplying by 100. The resulting product indicates the percentage of intervals during which the behavior was observed to occur. Converting to a percentage allows for comparisons across intervals of varying lengths.

Interval recording is a preferred method when the target behavior occurs at a moderate but steady rate. It should be noted that interval recording tends to over- or underestimate the actual frequency of behaviors, depending on whether partial- or whole- interval recording is used. With partial-interval recording, behavior frequency tends to be overestimated. For example, if the target behavior occurs once every 30 seconds during a 5-minute observation, but each instance lasts only 2 seconds, the observer would record an X in each box. The resulting percentage is 100, which is interpreted to mean that the behavior occurred during 100% of the intervals observed. Although this is true, “100%” overestimates the actual time the person spent engaged in the behavior (which in this case is only 20 seconds out of a 5-minute observation). With whole-interval recording, underestimations are possible. For example, using the same data presented above, no Xs would be placed in any boxes, because the behavior never lasted an entire 30-second interval. The observer would interpret these data as indicating that the behavior occurred during 0% of the intervals observed. Although this is true, it underestimates the actual frequency. Typically, whole-interval recording is used only when the duration of the behavior is of concern.

One significant advantage of using interval recording is that it is easier than some other methods. Specifically, because behaviors are not being counted per se, the observer only needs to note whether or not

the behavior occurred during the interval. Regardless of the number of times the behavior occurs during an interval, only one X is marked in the box.

### **Momentary Time Sampling**

The second major type of interval recording is momentary time sampling. Like interval recording, time sampling begins with the observer determining the size of the interval desired. Intervals typically are shorter in time sampling than in partial- or whole-interval recording.

A grid is constructed, with each box representing one interval. The observer begins the observation by starting the timer, and then momentarily observes the student or client at the end of the interval. If the behavior was observed to be occurring at the moment observed, an X is placed in the box. The next interval immediately follows. The major difference between interval recording and time sampling is that in interval recording, all behaviors that are observed during the interval are recorded. In time sampling, only behaviors that are occurring at the end of the intervals are recorded. It is entirely possible that a behavior might occur during every interval but never be recorded as having occurred if the behavior does not happen to be occurring at the end of the interval. For this reason, time sampling is not a preferred method for behaviors that occur only briefly (e.g., hitting). It is relatively easy, like interval recording, because the observer needs to note only if the behavior was occurring at the end of the interval. To interpret time sampling data, the observer adds the number of times sampled during which the behavior was observed to occur (i.e., the number of Xs), divides the sum by the number of intervals observed, and then multiplies that number by 100. The resulting figure represents the percentage of times sampled during which the behavior was observed to occur.

The advantages of time sampling are its relative ease (as noted above), and the fact that between sampling points, the observer can perform other tasks (such as observing others in the vicinity). The major disadvantage of time sampling is that very little of the total observation time is spent actually observing the student or client. For example, assuming “momentary” means 1 second, a 5-minute observation divided into 10-second intervals would mean the observer would observe 30 times (i.e., 6 times per minute for 5 minutes) or for 30 seconds out of 5 minutes. Many behaviors that could be recorded during that time are

not recorded unless they happen to be occurring at the end of the interval.

### **Event or Frequency Recording**

Event or frequency recording involves recording the number of times a behavior is observed to occur during an observation period. This type of recording involves a count of the number of separate instances of the behavior. An observer using event recording records the time at which the observation starts. The observer then notes each time the behavior either begins or ends, usually by using tally marks on a piece of paper (if a computer is not being used). At the end of the observation period, the observer adds the number of tally marks. The data can be interpreted as the number of times the behavior occurred. If comparisons across observations of different lengths are desired, the data can be recorded as a rate. For example, if 10 behaviors occurred during a 10-minute observation, the rate would be 1 behavior per minute.

Although event or frequency recording sounds simple, it is actually more difficult than either interval recording or time sampling. In the latter two methods, the observer needs to note only whether the behavior was occurring at the time of the observation. With event recording, the observer needs to know when a behavior either starts or stops. Therefore, it is imperative that behavioral definitions are written comprehensively enough to make this determination. For example, if a person engages in a self-injurious behavior for 3 seconds, pauses for 1 second, and then resumes the behavior, is this counted as one event or two events? The answer needs to be available in the definition of the behavior being used for the purpose of the observation.

Sometimes event recording can be used without the need for an observer actually seeing the behavior occur. Many behaviors produce *permanent products* that can be counted. Examples include the number of math worksheet problems completed and the number of days a student is tardy for school (using attendance records). The use of permanent products is desired over live observation because of its efficiency and verifiability. This is especially true for behaviors that occur very infrequently. Infrequent behaviors are very difficult to “catch” during an observation. With permanent products, behaviors can be “observed” after the fact.

Event recording is easily understandable to those not trained in behavioral observation, as it involves

counting behaviors. Assuming behavioral definitions are written to discriminate between instances of a behavior, event recording is a good choice for recording the frequency of a behavior. Its disadvantages include, as mentioned above, the requirement of very precise behavioral definitions and the fact that it lacks utility for behaviors that are not easy to count (e.g., inattention) as well as for behaviors that occur very infrequently (if no permanent products result from the behavior).

### **Duration Recording**

Duration recording produces an estimate of the amount of time a person spends engaged in a particular behavior. This is the only method discussed thus far that allows one to make statements related to percentage of time spent engaged in a behavior (although interval recording and time sampling data are often misinterpreted as meaning this). Duration recording is a difficult recording method to use, because the observer needs to note when the behavior both begins and ends. As such, behavioral definition specificity is imperative with this method.

Duration recording begins with the observer watching for the target behavior to begin. A stopwatch is started at that time, and then stopped when the behavior ends. The intervening time is recorded and the stopwatch is reset. This procedure is continued for the rest of the observation period. Subsequent to the observation, the total amount of time spent engaged in the behavior is computed by adding each of the amounts of time for individual instances of the behavior. Typically, that sum is divided by the number of instances of the behavior to obtain an average duration of each behavior. Because each recorded amount of time also corresponds to one behavior, duration recording also provides event or frequency recording data.

Duration recording provides very useful information, but it is difficult to use. Furthermore, it is only recommended if the duration of the behavior is a concern. For example, behaviors such as smoking or hitting are not particularly amenable to duration recording, because what is of most concern is the frequency of smoking or hitting (not how long they last). However, for behaviors such as tantrums or daydreaming, the goal may be to decrease their duration.

### **Latency Recording**

Latency recording is a very specific observation method that provides information about the amount of

time that elapses between an environmental event and the commencement or completion of a target behavior. Most typically, this method is used to determine the amount of time it takes for a person to comply with a command. In this case, the environmental event is the command, and the target behavior is compliance with that command. This method is very difficult to use, because not only does “compliance” need to be very solidly defined, but the event (i.e., command) also needs to be identifiable.

With latency recording, the observer starts the stopwatch when a command is given, and stops it when the client either begins to comply or has complied completely with the command. It is the observer’s choice whether to measure the time to beginning compliance or completing the task, but whatever method is chosen needs to be used consistently. The decision is likely to be based on the commands themselves (i.e., the behavior being requested), and characteristics of the client. For example, if the client typically begins to comply immediately when asked to brush his or her teeth, but then becomes distracted and never finishes the task, the observer would likely record time to completion of the task.

Regardless of method, once the client has satisfied the condition, the observer notes the time that elapsed, and he or she resets the stopwatch until the next command is given. This procedure is repeated for the duration of the observation period. Afterwards, the observer adds the elapsed time for each command and divides by the number of commands. This produces an average amount of time to compliance. It should be noted that compliance might not occur with some commands. In those cases, the observer would note that there was no compliance and restart the stopwatch when the next command is given. When interpreting results, it is important to note how many instances of noncompliance were observed.

### **Other Methods of Observation**

With the exception of duration and latency recording, each of the methods discussed above addresses behavioral frequency. As discussed earlier, observations may be made of frequency, magnitude/intensity, and duration. Duration recording and latency recording are both examples of methods for measuring duration of behaviors. Typically, behavioral magnitude/intensity is assessed by assigning a rating to the magnitude of a behavior (sometimes referred to as *performance-based behavioral recording*). Rating

scales may be developed to measure behavioral magnitude during a particular observation.

The validity of this method may be unknown, because validity is typically not determined for measures created for use with a single client. Some published procedures are available for particular behaviors (e.g., self-injurious behavior), but most often scales are created for use with particular clients. Measuring behavioral magnitude/intensity can be difficult, because different levels of magnitude need to be defined. For example, if the magnitude/intensity of social withdrawal is being measured using a scale of 1 to 4, definitions of what specific behaviors or characteristics constitute each of those ratings need to be written.

In addition to serving as a measure of behavior frequency, permanent products can also be used as a measure of behavior intensity. For example, the magnitude or intensity of trichotillomania (i.e., compulsive hair pulling) can be assessed by measuring the size of patches of pulled out or thin hair. The amount of bedwetting can be observed by measuring the size of wet spots on a bed. These behaviors leave permanent products that make actual observation of the behaviors unnecessary.

### Observation With Published Instruments

Several commercially available behavior-rating scales include forms for behavioral observation. Two of the more widely used include the Behavior Assessment System for Children—2nd Edition (BASC-2) and the Achenbach System of Empirically Based Assessment (ASEBA). The BASC-2's Student Observation System uses a momentary time sampling format for rating a variety of maladaptive and adaptive behaviors that are also included in other BASC-2 components (e.g., parent and teacher rating forms). The ASEBA includes a Direct Observation Form that includes 96 problem behaviors that are also represented on other ASEBA forms. Unlike the BASC-2 Student Observation System, the Direct Observation Form involves observing the student and recording behavior for a 10-minute period, then rating on problem behaviors observed during that time.

### Technology and Behavioral Observation

Increasingly, behavioral observations are being conducted using various computer-based tools and programs. Software for personal computers and hand-held

devices is often used for observations. These programs decrease observer error (e.g., observers are prompted to record behavior, eliminating the requirement for observers to keep track of time while observing), compile data collected in a format easily interpretable by the professionals involved, and allow for more sophisticated observational strategies. For example, some programs allow for the assessment of sequential conditions for behaviors. This possibility allows the observer to measure the likelihood of a particular behavior occurring, given the behavior that occurred before it. In other words, it allows predictions of behavioral probabilities.

## Issues in Behavioral Observations

### *Assessment Reactivity*

Because observers are in the physical presence of the client while collecting behavioral observation data, there is the potential for the procedure itself to change the client's behavior. This is referred to as *assessment reactivity*. Assessment reactivity can significantly affect the validity of observation data, so steps need to be taken to minimize its effects. The most common step addressed in the literature is to allow the client time to habituate to the observer's presence and activities. Habituation refers to a process whereby a person, upon prolonged exposure to a stimulus, stops responding to that stimulus. In the case of behavioral observation, the stimulus is the observer and the response is the change in typical behavior. Habituation can be achieved by allowing the client to get used to the observer's presence before any data are collected. Habituation is easier to achieve if the observer is as unobtrusive as possible. Sitting slightly behind but to the side of the person being observed is sometimes helpful.

### *Reliability*

Reliability refers to the consistency of results obtained from an assessment procedure, and it is important for the purposes of behavioral observation. There are several types of reliability, including internal consistency, test-retest, and inter-rater reliability. The first two are less applicable than the third for behavioral observation. With regard to test-retest reliability, for example, behaviors are not expected to remain stable over time, so low retest reliability is less a function of the instrumentation being used than the characteristics being assessed. Inter-rater reliability is

an important concept in behavioral assessment, however. It is important that two observers agree on whether targeted behaviors are occurring. Strong inter-rater reliability depends heavily upon solid behavioral definitions and comprehensive training for behavioral observers.

### Defining Behaviors

Behavioral definitions should have several characteristics. They should be objective, clear, and complete. Objective means the definition should include only observable aspects of the behavior. No inferences or judgments should be necessary when using the definition. The definition should be clear, meaning that it is understandable to any person who would want to conduct observations using the definition. Finally, the definition should be complete. It should delineate the bounds of the behavior, so that decisions can be made about whether a particular behavior represents an instance of the target behavior being observed.

### Using Behavioral Observation Results

Results of behavioral observations are typically used for three purposes related to intervention planning. First, they are used as a baseline of current levels of behavior. A baseline tells the professionals involved what to expect in the future if no intervention is to occur with an individual. Baseline data are also used for the second purpose—namely, the formulation of goals. Goals should be based on current levels of behavior. To not use baseline data in formulating goals is to risk setting goals that are unrealistic or too lenient. The third purpose for which results of behavioral observation are used is to measure outcomes. If initial observation data are used to determine baseline levels of behavior and for goal setting, later data can be used as a measure of whether interventions are successful. If data are being collected on a problem behavior, the behavior should decrease in frequency, magnitude, or duration if an intervention is successful. Conversely, if data are collected on an appropriate behavior, occurrences of the behavior should increase.

Behavioral observations are also conducted for research purposes. The data may be used to describe the behavior of an individual or group, or they may be used to measure change in behavior contingent upon some environmental manipulation or individual treatment. Sometimes in research, sophisticated coding

schemes are used to categorize or describe the behaviors observed, but they typically involve the use of one or more of the methods described above.

## BEHAVIOR ASSESSMENT SYSTEM FOR CHILDREN, SECOND EDITION

---

The Behavior Assessment System for Children, Second Edition (BASC-2) is used to facilitate differential diagnosis in individuals ages 2 to 25 years old. The BASC-2 comprises three forms: the Teacher Rating Scale (TRS), the Parent Rating Scale (PRS), and the Self-Report of Personality (SRP). The Teacher Rating Scale and the Parent Rating Scale have three versions delineated by age: preschool (2 through 5), child (6 through 11), and adolescent (12 through 21). Likewise, the SRP includes three forms differentiated by age: 8 through 11, 12 through 21, and 18 through 25. Both the PRS and SRP are available in Spanish for individuals living in the United States.

Informants—parents and teachers completing the relevant forms—provide ratings based on a 4-point response scale, ranging from *never* to *almost always*. The SRP includes items rated on a 2-point response

scale—*true* or *false*—while other items use a 4-point response scale. The BASC can be scored by hand or with computer software, which provides percentile ranks and *T* scores ( $M = 50$ ,  $SD = 10$ ). Interpretive information is provided by composite, primary, and (optional) content scales. In addition, the BASC-2 includes a Behavioral Symptoms Index and four composite scores, which offer broad estimates of behavioral problems and individual strengths.

The general norm sample included approximately 13,000 individuals. Data were collected from 375 sites, located in 257 cities, in 40 states across the country. Data collection sites included schools, mental health clinics, and day care facilities. General norm samples—collected from general-education classrooms—were similar to U.S. population estimates on specific variables: socioeconomic status, race/ethnicity, gender, and geographic region. Clinical norm samples did not reflect U.S. census estimates.

Coefficient alpha reliabilities for the Behavioral Symptom Index and composite scores range from .94 to .97 on Externalizing Problems, .87 to .92 on Internalizing Problems, .91 to .97 on Adaptive Skills, .92 to .94 on School Problems, and .95 to .97 on the Behavioral Symptoms Index. Clinical norm samples produced similar correlations on parallel composites. Test-retest reliability coefficients are based on individuals—including persons from general and clinical samples—rated by the same teacher. The stability of the BASC-2, measured with a retest interval of 8 to 65 days, is adequate, with coefficients ranging from .78 to .91. Inter-rater reliability estimates were based on responses of two raters. The rating intervals range from 0 to 62 days. Correlations for composite scores range from .53 to .65.

Construct validity, evidenced by factor analysis, supports four factors for the Teacher Rating Scale and Self-Report of Personality: Externalizing Problems, Internalizing Problems, Adaptability, and School Problems. Factor analysis for the PRS evidences identical factors, excluding School Problems. Criterion related validity, as shown by correlations between similar composite scores, was acceptable. For example, correlations between Externalizing Problems scores range from .73 to .84; between Internalizing Problems scores, the range is from .65 to .75.

The BASC-2 provides practitioners with a multi-method and multidimensional assessment of behavioral, social, and emotional competencies. It is an attractive measure for several reasons. Data are gathered from a

variety of sources, in multiple settings, that represent pertinent diagnostic information. Additionally, the BASC-2 provides estimates of problematic behavior and positive attributes; therefore, desirable qualities can be incorporated into treatment planning. For the purposes of classification and diagnosis, comprehensive assessment—including a functional behavior analysis—is quintessential. Therefore, the BASC-2 is one of the many sources of a thorough assessment.

## BEHAVIOR RATING SCALES

---

Behavior rating scales are one of the oldest assessment tools used in mental health, education, and research. These scales typically assess problem behaviors, social skills, and emotional functioning; are widely employed in the assessment of personality development, adaptive behavior, and social-emotional functioning; and aid in diagnostic decision making and in planning treatment and education. These well-proven scales are easy to administer, score, and interpret and have become an integral part of the clinical and school assessment of children and adolescents.

A variety of behavior rating scales are available for use in clinical practice and research. The majority of behavior rating scales are intended for use with children, though a handful can be used with adults. The use of behavior rating scales in the evaluation of adult clients is gaining popularity. There are a number of advantages of using behavior rating scales: They quantify and systematically organize client information, administration and scoring is generally quick and easy, most allow for

comparison of ratings across respondents and/or settings, and because these are norm-referenced instruments, the client's symptoms and behaviors can be compared with those of his or her peers.

Behavior rating scales help clinicians obtain information from parents, teachers, and others about a client's symptoms and functioning in various settings, which is necessary for an appropriate assessment for a number of disorders as well as for treatment monitoring. Such instruments are generally only one component of a comprehensive evaluation, which commonly includes direct observation of the client, objective and projective measures, and interviews. Most behavior rating scales are normed using nationally representative samples, but they also often include clinical norms as well, which allows for a variety of behavior comparisons. Ideally, the rating scale used should be normed to similar client populations, so results indicate if a client's skill, behavior, or emotional status is typical or significantly different from that of peer groups.

### Uses of Behavior Rating Scales

The most common use of behavior rating scales is in the diagnosis of mental and behavioral disorders. The content of behavior rating scales often conforms to *Diagnostic and Statistical Manual of Mental Disorders (DSM)* diagnostic criteria, though it often differs in the way the symptoms are quantified as well as in the way the symptoms are combined. In the educational setting, these scales are also used to help determine eligibility for special education and other programs. In addition, they are used to plan interventions and to monitor symptoms and behavior during and following treatment.

There is ample empirical support for the validity of using behavior rating scales for diagnostic and placement decision making. However, the use of these scales in planning interventions and monitoring client progress has not yet been adequately validated. Because of this, behavior rating scales should never be the sole method used to monitor response to treatment, though behavior rating scales do have a place as one piece of a multimodal method. For example, direct observations and rating scales are considered the best methods to evaluate the effects of medication trials on a child's behavior. When used in conjunction with direct observations, behavior rating scales may give an indication of differences in behavior across settings or differences in the perception of the client's behavior by significant others in his or her life. It is

always important to ensure that the scale is appropriate for this use. If a behavior rating scale is used to monitor a behavioral intervention, care should be taken to make sure the scale aligns with this goal. Many scales monitor reductions in negative behaviors, but most lack items that measure positive replacement behaviors.

Behavior rating scales typically quantify the severity of the behaviors or symptoms on Likert scales (e.g., 0—*not present* to 4—*severe*) or the frequency that the behavior or symptom is observed (e.g., 0—*never* to 4—*almost always*). Scores on the scale or subscales are then summed and converted to a standard score such as a *T* score, which allows for comparison of the frequency of a variety of behaviors to norms for a client's gender and/or age group. These data are critical for determining the clinical significance of the client's symptoms and behaviors.

### Types of Behavior Rating Scales

Many of the newer behavior rating scales use a comprehensive, multidimensional approach to the assessment of behavior. For example, many scales include observer/informant and self-report forms. In addition, clinicians can choose from global scales that assess multiple domains of functioning or scales that focus on a specific dimension of behavior.

#### Observer/Informant Scales

Significant others, such as parents and teachers, can provide valuable information about a client's behavior that would otherwise be unavailable to the clinician. This information can be extremely helpful as part of case conceptualization, especially with child clients. Informant scales assess the degree or frequency of certain behaviors or skills based on the respondent's perceptions. The rater must be very familiar with the client to provide useful information, and using multiple raters helps reduce biased perceptions. The psychologist's report should note who provided the ratings and describe his or her relationship to the client.

#### Self-Report Scales

Older child clients and adults are often asked to provide ratings of their own behavior, feelings, and skills. These measures are similar, or even identical, to other rating scales and are often used in conjunction

with teacher or parent ratings. It can be helpful to compare how clients perceive themselves relative to how others perceive them. However, it is important to note that in psychiatric disorders where either the client's verbal capacity (e.g., autism, dementia) or insight (e.g., psychotic conditions) is compromised, self-rating scales have very little value.

### ***Single Domain Scales***

Scales that assess one specific area allow for focused, in-depth evaluation of a behavior or particular area of functioning. Focusing on a single dimension of behavior may be warranted when the referral question is limited to a specific concern. Most of these scales are intended to assess attention deficit hyperactivity disorder (AD/HD), social skills, or conduct problems. These measures are often used subsequent to the use of multidomain scales that have identified one or more areas of concern.

### ***Multidomain Scales***

Multidomain behavior rating scales assess a broad array of social, emotional, and behavioral functioning. The use of these scales has increased dramatically in popularity due to research findings that many individuals, particularly children, tend to have difficulties in multiple areas. For example, research in developmental psychopathology suggests a high degree of comorbidity among the social, emotional, and behavioral domains. Thus, multidomain behavior rating scales allow the clinician to obtain information about a variety of areas of functioning with one tool.

## **Widely Used Behavior Rating Scales**

There are many different behavior rating scales available to clinicians. The most commonly used scales are the Achenbach Scales, the Behavior Assessment System for Children (BASC-2), the Connors instruments, the Attention Deficit Disorders Evaluation Scale (ADDES), the ADD-H Comprehensive Teacher Rating Scale (ACTeRS), the ADHD Rating Scale-IV, the Behavior Rating Profile (BRP-2), the Burk's Behavior Rating Scales (BBRS), and the Social-Emotional Dimension Scale (SEDS-2). One other behavior rating scale that is quickly gaining popularity is the Behavior Rating Scale of Executive Function (BRIEF). Although this list does not cover the full range of available

behavior rating scales, it is a good representation of scales that are widely or typically used, as determined by surveys of practitioners.

### ***Achenbach Scales***

The Achenbach System of Empirically Based Assessment (ASEBA) offers a comprehensive approach to assessing adaptive and maladaptive functioning. These multidomain instruments allow for multi-informant assessment across the age span (1.5 to 90 years). ASEBA instruments allow for documentation of clients' functioning in terms of both quantitative scores and individualized descriptions in respondents' own words. Descriptions include what concerns respondents most about the client, the best things about the client, and details of competencies and problems that are not captured by quantitative scores alone. Evidence of adequate psychometrics of the Achenbach scales is provided in the test manual. In addition, numerous studies have demonstrated significant associations between ASEBA scores and both diagnostic and special education categories.

ASEBA behavior rating scales include the Child Behavior Checklist (CBCL), the Caregiver-Teacher Report Form (C-TRF), the Teacher Report Form (TRF), the Youth Self-Report (YSR), the Adult Behavior Checklist (ABCL), the Adult Self-Report (ASR), the Older Adult Behavior Checklist (OABCL), and the Older Adult Self-Report (OASR). The ASEBA informant scales generally take 15 to 20 minutes to complete, while the self-report scales take 20 to 30 minutes. Forms can be hand- or computer-scored.

#### **CBCL**

The CBCL/6–18 obtains reports from parents, other close relatives, and/or guardians regarding children's competencies and behavioral or emotional difficulties. The CBCL/6–18 has 112 items that describe specific behavioral and emotional problems, plus two open-ended items for reporting additional problems. Parents rate their child for how true each item is using a 3-point scale from 0 (*not true*) to 2 (*very true or often true*). Parents also provide information for 20 competence items covering their child's activities, social relations, and school performance.

The CBCL/6–18 scoring profile provides *T* scores and percentiles for three competence scales (Activities, Social, and School), Total Competence, eight

syndromes, six *DSM*-oriented scales, and Internalizing, Externalizing, and Total Problems. The syndrome scales include Aggressive Behavior, Anxious/Depressed, Attention Problems, Rule-Breaking Behavior, Social Problems, Somatic Complaints, Thought Problems, and Withdrawn/Depressed. The six *DSM*-oriented scales are Affective Problems, Anxiety Problems, Somatic Problems, Attention Deficit/Hyperactivity Problems, Oppositional Defiant Problems, and Conduct Problems.

The CBCL for preschool-age children (CBCL/1½–5) is used to obtain parents' reports of their 1½- to 5-year-old child's competencies and problems. It obtains ratings of 99 problem items, plus descriptions of problems, disabilities, what concerns parents most about their child, and the best things about the child. Items combine to form the following scales: Emotionally Reactive, Anxious/Depressed, Somatic Complaints, Withdrawn, Attention Problems, Aggressive Behavior, and Sleep Problems. Scores on Internalizing, Externalizing, and Total Problems composite scales are also provided.

Like the CBCL/6–18, the preschool profile features *DSM*-oriented scales in addition to the empirically based scales. Scales were constructed for the following five *DSM*-oriented categories: Affective Problems, Anxiety Problems, Attention Deficit/Hyperactivity Problems, Oppositional Defiant Problems, and Pervasive Developmental Problems. The CBCL/1½–5 also includes the Language Development Survey (LDS), which uses parents' reports to assess children's expressive vocabularies and word combinations as well as risk factors for language delays. The LDS indicates whether a child's vocabulary and word combinations are delayed relative to norms for children ages 18 to 35 months. The LDS can also be completed for language-delayed older children.

#### TRF and C-TRF/1½–5

The TRF is designed to obtain teachers' reports of children's academic performance, adaptive functioning, and behavioral or emotional problems. The scale has 118 problem items, of which 93 have counterparts on the CBCL/6–18. The remaining items concern school behaviors that parents would not observe, such as difficulty following directions and or disturbance of other pupils. Teachers rate the child for how true each item is using the same 3-point response scale used on the CBCL/6–18.

Scores for Academic Performance, Total Adaptive Functioning, the eight cross-informant syndrome

scales, and the six *DSM*-oriented scales can be obtained. Like the CBCL, the TRF also provides Internalizing, Externalizing, and Total Problems composite scores.

For 1½- to 5-year-olds, preschool teachers and day care providers can complete the Caregiver-Teacher Report Form for Ages 1½–5 (C-TRF/1½–5). The C-TRF consists of 99 items, plus descriptions of problems, disabilities, what concerns the respondent most about the child, and the best things about the child.

#### YSR

The YSR is a self-report scale that can be completed by youths who have fifth grade reading skills, or it can be administered orally. Its competence and problem items generally parallel those of the CBCL/6–18; plus it contains items covering physical problems, concerns, and strengths that require open-ended responses. In addition, the YSR has 14 socially desirable items that most youths endorse about themselves. The YSR scoring profile includes two competence scales (Activities and Social), Total Competence, the eight cross-informant syndrome scales, and the six *DSM*-oriented scales that are also scored on the CBCL and TRF, and Internalizing, Externalizing, and Total Problems scales.

#### ABCL

The ASEBA is one of the few assessment systems with a behavior rating scale intended for use with adults. The ABCL is for clients ages 18 to 59. The client's spouse or partner typically serves as the respondent, but any adult who is close to the client can complete the ABCL. The profiles of the ABCL include scales for Adaptive Functioning, Empirically Based Syndromes, Substance Use, Internalizing, Externalizing, and Total Problems. The ABCL profiles also feature new *DSM*-oriented scales and a Critical Items scale consisting of items of particular concern to clinicians.

The following cross-informant syndromes were derived for the ABCL: Anxious/Depressed, Withdrawn, Somatic Complaints, Thought Problems, Attention Problems, Aggressive Behavior, Rule-Breaking Behavior, and Intrusive. The ABCL and ASR have parallel Substance Use, Critical Items, Internalizing, Externalizing, and Total Problems scales. The *DSM*-oriented scales are Depressive Problems, Anxiety Problems, Somatic Problems, Avoidant Personality

Problems, Attention Deficit/Hyperactivity Problems, and Antisocial Personality Problems. For older clients (ages 60–90+), clinicians can use the OABCL.

### ASR

The Adult Self-Report (ASR) is normed for clients 18 to 59 years. Like the YSR, the ASR profiles include scores for Adaptive Functioning, cross-informant empirically based syndromes, Substance Use, Internalizing, Externalizing, and Total Problems. In addition, the ASR profiles feature the *DSM*-oriented scales that are scored on the ABCL and a Critical Items scale. Older clients (60–90+ years) can complete the OASR.

### BASC-2

The BASC-2 system is a set of tools that assess the behaviors and emotions of preschool- through college-age individuals and is respected for its developmental sensitivity. The scales of the BASC-2 were first defined conceptually and then confirmed via factor analysis. In addition to evaluating personality and behavioral problems and emotional disturbances, the instruments identify positive attributes that can be capitalized on in the treatment process.

The BASC-2 system enables assessment from three vantage points: self, teacher, and parent or caregiver. Thus, information from multiple sources can be compared using instruments with overlapping norms to help achieve reliable and accurate diagnoses. The system provides an extensive view of adaptive and maladaptive behavior and measures areas important for both Individuals with Disabilities Education Act and *DSM-IV* classifications. Various types of validity checks are incorporated into the BASC-2 to help the clinician detect careless or untruthful responding, misunderstanding, or other threats to validity.

The BASC-2 Parent Rating Scales (PRS) and Teacher Rating Scales (TRS) are normed for individuals ages 2 years to 21 years, 11 months. These scales can typically be completed in 10 to 20 minutes. The Self-Report Scale (SRP) can be completed by individuals 8 years through college-age and takes about 30 minutes to complete.

*T* scores and percentiles for both general population and clinical norms can be obtained for all measures, and computer scoring and interpretation programs are

available. Reliability and validity evidence is supportive of this measure.

### PRS

The PRS assesses numerous aspects of behavior, including both adaptive (healthy) and clinical (problem) behaviors in the community and home settings. Parents or caregivers can complete forms for one of three age levels—preschool (ages 2 to 5), child (ages 6 to 11), and adolescent (ages 12 to 21)—in 10 to 20 minutes. The PRS contains 134 to 160 items that describe specific behaviors that are rated on a 4-point scale of frequency, ranging from *never* to *almost always*. The PRS clinical scales include Hyperactivity, Attention Problems, Aggression, Conduct Problems, Atypicality, Anxiety, Somatization, Withdrawal, and Depression. The adaptive scales are Activities of Daily Living, Adaptability, Social Skills, Functional Communication, and Leadership.

The clinical scales on the PRS combine to form three composite scales: Internalizing Problems, Externalizing Problems, and a Behavioral Symptoms Index. An Adaptive Skills Composite score is formed from scores on the adaptive scales. Validity and response set indexes used to help judge the quality of completed forms are also available. One additional tool is a list of Critical Items that may have clinical importance of their own. Some of these items are included solely for this singular attention and are not part of any scale (e.g., “Has a hearing problem”) while others have special significance such as “Says, ‘I wish I were dead.’”

### TRS

Like the PRS, the TRS includes forms for three age levels and uses a four-choice response format for the 100+ items. Teachers or other qualified observers provide information about adaptive and problem behaviors in the preschool or school setting. Clinical scales on the TRS parallel those on the PRS but also include a Learning Problems scale for those between 6 and 21 years of age. The TRS adaptive scales are also identical to those on the PRS except for a Study Skills scale that is substituted for the Activities of Daily Living scale. The following composite scores are reported on the TRS profile: Internalizing Problems, Externalizing Problems, School Problems, Behavioral Symptoms Index, and Adaptive Skills.

### SRP

The SRP helps provide insight into an individual's thoughts and feelings. It contains 139 to 185 true/false and multiple choice (*never* to *always*) items and measures the following clinical areas: Attitude to School, Attitude to Teachers, Sensation Seeking (ages 12 to 21 only), Atypicality, Locus of Control, Social Stress, Anxiety, Depression, Sense of Inadequacy, Somatization, Attention Problems, and Hyperactivity. Positive psychological adjustment is measured via the adaptive scales (Relations with Parents, Interpersonal Relations, Self-Esteem, and Self-Reliance). Four composite scores are provided on the profile: School Problems, Internalizing Problems, Externalizing Problems, and Personal Adjustment.

### Conners Scales

First published in 1989, the Conners Rating Scales (CRS) is one of the most popular tools for assessing ADHD and other disruptive disorders in children and adolescents. The 1997 revised edition, the CRS-R, is linked to the *DSM-IV* and allows for multimodal evaluation of problem behaviors. There are long and short versions of each type of scale (parent, teacher, and self-report) that use a 4-point scale: *not at all* to *very much*. The short scales take 5 to 10 minutes to administer and the long scales take 15 to 20 minutes. Both the parent and teacher rating scales are used to characterize the behaviors of children and adolescents ages 3 to 17, while the self-report scales can be completed by 12- to 17-year-olds. The Conners manuals provide evidence of adequate psychometric properties of these measures.

The 10 scales scored on the long parent and teacher forms are Oppositional, Cognitive Problems/Inattention, Hyperactivity, Anxious-Shy, Perfectionism, Social Problems, Psychosomatic, *DSM-IV* Symptom Subscales, Global Index (formerly the Hyperactivity Index), and AD/HD Index. The short forms offer scores on four scales: Oppositional, Cognitive Problems/Inattention, Hyperactivity, and AD/HD Index.

The Adolescent Self Report long form has 87 items and 8 scales: Family, Emotional, Conduct, Cognitive, Anger Control Problems, Hyperactivity, AD/HD Index, and *DSM-IV* Symptoms Subscales, while the short self-report form has four scales: Conduct Problems, Cognitive Problems, Hyperactivity/Impulsive, and AD/HD Index.

The Conners Adult AD/HD Rating Scales (CAARS) is used to assess AD/HD in adults. It can be used with individuals 18 years and older and includes both observer and self-report forms. The CAARS quantitatively measures AD/HD symptoms across clinically significant domains while examining the manifestations of AD/HD in adults based on scientific literature and the authors' clinical experience.

The self-report (CAARS-S) and observer forms (CAARS-O) address the same behaviors and contain identical scales, subscales, and indexes. *T* scores are produced for each scale, subscale, and index. Separate norms are available by gender and age-group intervals (18–29, 30–39, 40–49, and 50+ years).

Like the CRS, the CAARS has both long and short versions. The long versions comprise 66 items that assess a broad range of problem behaviors. They include a variety of factor-derived and *DSM*-derived subscales as well as three *DSM-IV* symptom measures (Inattentive, Hyperactive-Impulsive, and Total ADHD Symptoms), a 12-item AD/HD Index, and an Inconsistency Index for identifying random or careless responding. The short self-report (CAARS-S: S) and observer (CAARS-O: S) forms contain 26 items that are abbreviated versions of the factor-derived subscales that appear in the long versions. The AD/HD Index and the Inconsistency Index are also incorporated.

### BRP-2, BBRS, and SEDS-2

Although the BRP-2, the BBRS, and the SEDS-2 still rank among the most frequently used behavior rating scales, they are being used with much less regularity than in the past. These scales are all multidimensional scales designed to be used with children. The BRP-2 has parent, teacher, and self-report forms; the BBRS has a single form that can be administered to parents and teachers, and the SEDS uses a teacher form only.

Although each of these scales can provide some helpful information, they all have limitations that the Achenbach, BASC-2, and Conners scales do not. For example, the BBRS has fairly weak psychometric properties, and the authors used a rather narrow standardization sample when norming the instrument. The BRP-2's item content is limited, and the items lack behavioral specificity. Finally, the *T* scores on the SEDS-2 cannot be compared across scales, limiting the scale's usefulness.

## Measures for Assessment of ADHD

The most widely used measures of symptoms of AD/HD—the ADDES, ACTeRS and ADHD Rating Scale-IV—all use parent and teacher forms. The respondents rate the child client on characteristics typically associated with attention deficit disorders: inattention, impulsivity, and hyperactivity. All of these scales are generally easy to administer and score and provide helpful information that can contribute to the diagnostic process. However, considering the complexity of AD/HD, as well as the literature on comorbidity, it is wise to consider using a multidimensional instrument such as the CBCL or the BASC, either of which is more likely to detect evidence of commonly comorbid conditions such as a learning disability, oppositional defiant disorder, conduct disorder, obsessive-compulsive disorder, or depression.

## BRIEF

Unlike other behavior rating scales, the BRIEF is designed specifically to assess impairment of executive function. According to the user manual, executive functions are those processes responsible for purposeful, goal-directed, and problem-solving behavior. The BRIEF uses parent and teacher forms that can be used with children ages 5 to 18. Both forms have 86 items and take 10 to 15 minutes to administer. Scoring by hand takes 15 to 20 minutes, and computer scoring software is available.

The BRIEF comprises two validity scales (Negativity and Inconsistency of Responses) and eight nonoverlapping theoretically and empirically derived clinical scales that measure various aspects of executive functioning. The clinical scales include Inhibit (control impulses, stop behavior), Shift (move freely from one activity or situation to another; problem-solve flexibly), Emotional Control (modulate emotional responses appropriately), Initiate (begin activity, generate ideas), Working Memory (hold information in mind to complete a task), Plan/Organize (anticipate future events, set goals, develop steps), and Monitor (check work, assess own performance). These scales form two broader indexes, Behavioral Regulation and Metacognition, as well as a Global Executive Composite score.

The family of BRIEF rating scales includes a preschool version for ages 3 to 5 years (BRIEF-P), a self-report form for adolescents ages 13 to 18 years (BRIEF-SR), and adult observer and self-report forms

for individuals 18 to 90 years of age (BRIEF-A). Each of these scales parallels the original BRIEF in terms of format and conceptual framework. The BRIEF is useful in evaluating individuals with a wide spectrum of developmental and acquired neurological conditions and psychiatric disorders such as learning disabilities, AD/HD, Tourette's disorder, traumatic brain injury, pervasive developmental disorders or autism, lead exposure, multiple sclerosis, dementias, and schizophrenia.

## BEREAVEMENT

Bereavement refers to the experience of loss of a person through death. Grief is the most typical response of survivors to bereavement, while mourning is the expression by the bereaved of thoughts and feelings in culturally patterned ways. In our society, typical responses include confusion, despair, forgetfulness, sleep disturbances, extended periods of crying, and a variety of physical symptoms.

### The Contexts of Bereavement, Grief, and Mourning

The range and intensity of grief reactions vary as a function of the family position and life stages of the people involved, the nature of their relationships, and the manner in which the death occurred. (See *Death and Dying* for a discussion of the latter.)

#### *Loss of a Child*

When a child dies, parents generally are stunned by the violation of their presumption that children don't die, that they should bury their parents. Lost as well are parental hopes and dreams for the dead child along with belief systems about what was assumed to be a more orderly and just universe. Parents tend to have a strong need to tell their story and often search for reassurance that the child who died is all right.

The impact of miscarriage or early neonatal death often is unrecognized, and the parents' grief is minimized or overlooked. Parents who have lost a child under such circumstances also may fear becoming pregnant again or feel guilty about being happy if and when they do.

Parents' ability to care for surviving children is likely to be compromised. They may become either overprotective or withdraw in the face of their own confusion as they seek to make sense out of what has occurred. Additionally, the relationship between grieving parents may experience challenges. Parental conflict may occur given different mourning styles, an inability to meet each other's needs, miscommunication, differences in readiness to return to sexual intimacy or social activities, and disagreement about religious beliefs. Parents also may differ regarding the handling of the dead child's clothing, room, and possessions.

#### *Loss of a Sibling*

Loss of both an important relationship and of appropriate parental support may occur with sibling loss. Children's sense of security may be threatened as parents behave differently, are inconsistent, appear vulnerable, refuse to reminisce about the dead sibling, and are unable to support their grieving processes. Insensitive behavior on the part of others may include failure to understand sibling grief and inquiries about their parents without first or ever asking how they are doing.

Sibling loss may increase children's perceptions of vulnerability to death and may be a confusing and lonely experience. Younger children may feel the burden of being a "replacement" for the dead child, and older children may experience survivor guilt. Adolescents must face death in addition to such developmental tasks as contemplating the meaning of life. Reactions include excessive guilt, distorted concepts of death, death phobia, religious confusion, and disruptions in behavior and cognitive functioning.

Sibling loss in adulthood may heighten awareness of one's own mortality. Loneliness and emptiness accompany the loss of an expected lifelong companion, or source of current and future support. Reactions due to a residue of pain from other losses likely to occur late in life are likely to resurface for older adults.

#### *Loss of a Parent*

The impact of parental death on children tends to have the greatest variation. It is an unthinkable and life-changing loss for young children; for older adults it is highly predictable and often assumed to be less disturbing. The level of cognitive and emotional maturation affects survivors' ability to understand the meaning of a parent's death.

Very young children may grieve, may continually request that the lost parent return, and may reject anyone who attempts to act as a substitute. Children between the ages of 2 and 5 may be helped to understand the meaning of death, can be dealt with in an honest, direct manner, and may regress in their behavior (e.g., bedwetting). Between ages 5 and 8, children may experience guilt about their parent's death or may deny that it is permanent. Between ages 8 and 12, children's reactions tend to mimic those of adults, including increased fears about both their own mortality and that of their surviving parent. For many

adults, the loss of a parent may be followed by an extended, often unanticipated, period of anguish and bereavement.

Daughters may feel more depressed than sons as they tend to remain more closely tied to their parents, even as adults. For adult daughters, mother loss may mean the loss of a friend and companion. For adult sons, grief at the death of a mother may be intense because, of the two parents, she was the one with whom they were able to be more open and expressive. Father loss is significant for both men and women, who tend to measure their sense of personal success against the standard set by their fathers, turn to them for advice and guidance regarding finances and careers, and seek their sanction for life choices.

### **Loss of a Spouse**

Spousal loss may shatter the survivor's sense of security. For both widows and widowers, the most severe reactions tend to occur when the death was unanticipated. Women often report that they feel abandoned, while husbands tend to describe a sense of dismemberment. Women generally cry more freely than men, who are more likely to behave according to societal constraints against emotional expression. Both men and women may feel angry, with women tending to describe a sense of injustice and men tending to experience guilt.

The death of a spouse for both young and middle-age couples is an occurrence out of time. Surviving spouses suddenly may find themselves single parents of school age or teenage children. Having launched children, they may have anticipated greater freedom and more opportunities to spend time together. While more expected, spousal loss late in life ends a relationship of great length and may be painful for different reasons. The challenges of loneliness and of making it alone are very real as remarriage becomes less likely the older the surviving spouse is; this is even more typical for women than for men.

Partnerships created in committed relationships often are comparable to marriages in terms of depth of emotion and shared hopes, expectations, and dreams. However, there generally are few legal and societal supports for surviving partners. *Lack of permission* to express grief appropriately or participate in funeral and burial arrangements and ceremonies is likely. In the case of an AIDS-related death, stigma may further complicate grief reactions.

### **Loss of an Extended Family Member or a Friend**

The role played by the person who died and the degree of emotional dependence between that person and the survivors affect the impact of losing a friend or extended family member. If similar the two are in age, the death may represent a reminder of one's own mortality. Grief may be unrecognized or unsupported, because others tend to judge significance based on the degree of kin-relationship. Absence from work to attend funerals may not be permissible, the deceased's close family members may not acknowledge or even be aware of the person's depth of grief, and external expressions of grief may be curtailed for fear of intruding on the immediate family. Loss of a coworker may be confusing, with colleagues unsure of how to behave with each other, unable to attend funerals or other rituals, wary of speaking about the dead person, and unsupported relative to their grief. The parents of children who lose a classmate may not understand the impact of this loss or take appropriate steps to deal with its ramifications. When a pet dies, others are unlikely to understand the depth of grief that may be felt.

## **Understanding Bereavement, Grief, and Mourning**

The responses of professionals to bereaved clients generally have been guided by two different models, with the degree of intensity and length of time in which reactions are considered appropriate much debated.

### **Classical Models of Grieving**

Based on the psychoanalytic perspectives of Sigmund Freud and Erich Lindemann and the attachment theory of John Bowlby, classical approaches describe grieving as a time-limited process characterized by 2 weeks of shock and intense grief, 2 months of strong grieving, and 2 years during which the grief decreases and bereaved individuals recover and return to full, normal functioning. The ultimate goal is detaching from emotional ties to the deceased and regaining the ability to form new relationships with the living. Grief is considered maladaptive when not resolved within the designated appropriate amount of time. The basic assumptions underlying this approach are that bereaved people go through predictable stages of grief, depression following loss is inevitable,

people who do not experience severe distress over the loss eventually will show some sign of psychopathology, and working through the loss is essential to recovery.

### ***Revised Model of Grieving***

Research conducted in the 1980s led to recognition of the importance of understanding grief in context and considering the bereaved person's belief systems and coping skills. Newer conclusions include that the grieving process may have no fixed endpoint and may last a lifetime; complete detachment from the deceased is neither desirable nor possible; bereaved persons may remain involved and connected to the deceased, often constructing inner representations of them; bereavement may take many forms; and the degree to which grief is adaptive or maladaptive must be determined on an individual basis. Coming to terms with the loss may be particularly difficult when the circumstances of the death represent a threat to one's worldview or when little social support is forthcoming. Those whose coping styles involve either avoidance or excessive rumination may have more difficulty dealing with bereavement. People who tend to be dependent or pessimistic, who lack self-control, or who are emotionally less stable also are likely to experience greater difficulty making the adjustments required.

### **Counseling the Bereaved**

Professionals are advised to just be "with" the bereaved, to allow them to cry, to rage, to despair, to express all of their feelings. Understanding anger as an essential component of grief is essential, as is sensitivity to irrationality in thoughts, feelings, and behaviors, with both acceptance and a focus on transforming guilt becoming important. Survivors may benefit from engaging in a process of forgiveness. Working to achieve justice for an act of wrongdoing may provide a useful outlet for frustration and impotence felt following a violent death. Helping survivors replace painful images with those more consistent with how the person looked when alive may be helpful. Giving time and attention to perceived loose ends may facilitate a sense of completion.

Funerals acknowledge survivors' loss and pain, allow for open expressions of grief, and offer opportunities for public recognition of the death and affirmation of the life of the person who died. They also

provide a setting in which to consider and speak about the meaning of both death and life while serving the public purpose of disposing appropriately of the body. In some religious traditions, funerals support the transition for the deceased while providing comfort for the bereaved. They also create a context that facilitates connection with a community of support.

Survivors may need help deciding what type of arrangements they desire and how they would like things to be handled. They also may need support as they meet with funeral directors and clergy persons. Helpers may provide information about options for caring for the body and preparing for burial or cremation. They may listen sensitively, explore possibilities, encourage survivors to trust their intuition about what seems right, and make suggestions and offer ideas based on experiences with others.

Ceremonies may be small or large, public or private, and may be planned to achieve many goals. They may fill a void, providing closure if no service was held at the time of the death, or they may supplement, satisfying a perceived need for something additional. Professionals may assist survivors in considering their goals and maintaining an emphasis on the strengths of everyone involved. They may suggest the inclusion or exclusion of others as appropriate. They also may emphasize the importance of affirmation for the survivors as well as for the deceased, remembering that their primary role is that of consultant rather than creator.

Daily life involves a series of rituals, including the ways we get up in the morning, fix and eat meals, prepare for bed, etc. All rituals and regular routines are likely to be disturbed by the death of a loved one, thereby increasing the sense of dislocation experienced by the bereaved. Recognition of their importance and a focus on adaptation of rituals may be important. Meaningful healing rituals also may be encouraged, including maintaining or transforming rooms; journaling; meditating or praying; designating time to grieve; wearing an article of clothing or jewelry that belonged to the person who died; dealing with holidays, birthdays, and anniversaries; lighting candles; creating scrapbooks, albums, or videotapes; writing letters; and volunteering or supporting a cause.

Making sense of loss is the last and most difficult step in the search for resolution. Assisting the bereaved in this regard may include assessing the role of religion or spirituality as resource or disappointment, listening carefully and offering questions or

reflections that test the logic of various lines of reasoning, recommending books, validating nontraditional explorations, suggesting explorations of death in other cultures, and confirming the possibility of reclaiming joy. Rather than getting over the loss, resolving grief may be understood as a process of acknowledgment, of learning to accept and to live with grief while at the same time being successful in reclaiming joy as an equally valid part of life.

## BINGHAM, ROSIE PHILLIPS (1949– )

---

Rosie Phillips Bingham has always been determined as well as a person of vision. It appears that these are values she learned from her parents growing up in poverty on a plantation in Mississippi with 11 siblings. During her childhood, she and one of her brothers contracted typhoid fever and spent nearly a month

in the hospital, where her mother stayed with them day and night despite having no accommodations (e.g., bed, chair, cot). Determination propelled her mother to sleep standing up or sitting on one of her children's beds, and undoubtedly Bingham carries the memory of this determination and tenacity with her.

At the age of 4, Bingham and her family moved from Mississippi to Memphis, Tennessee, where her father became a sanitation worker. He was involved in the 1968 sanitation strike that promoted equal wages and benefits for African American sanitation workers and sparked the attention of Dr. Martin Luther King, Jr., who visited the city to support these workers and was later assassinated there. Bingham must have also been influenced by her father's determination in seeking racial and economic equality as well as encouraged by her father's optimism that this type of equality was attainable.

Bingham was described as a "smart girl" growing up, and she immensely enjoyed reading books as a child, because books allowed her to escape her poverty. Her vision and imagination allowed her to take herself into another world. Because Bingham's family was poor, it was only through her intelligence and determination that she was able to attend Elmhurst College in Elmhurst, Illinois, and receive a bachelor of science degree in sociology and education. Bingham then went on to receive her master of arts degree in counseling and guidance and her doctorate in counseling psychology from Ohio State University.

In 1972, Bingham began her career as a psychologist and relied on the same determination and vision from her parents and from the civil rights movement in order to accomplish her goals and aspirations. First, Bingham became an assistant professor of psychology at Ohio Dominican College in Columbus, Ohio. She worked there for 6 years, focusing on college students' scholastic efficacy, before moving to the University of Florida in 1978. There, Bingham became a staff psychologist, adjunct professor, and finally associate director of the University of Florida Counseling Center. Her peers considered her determined, hard-working, and someone who could always recognize the big picture while also attending to the details. In addition, Bingham was described as always having a vision of how she and the center would accomplish their established goals and as an individual who would somehow find a way to bring this vision to fruition. While maintaining professional boundaries at the University of Florida, Bingham also established

lifelong friendships because of her good-natured humor and her ability to balance work with play.

In 1985, Bingham moved to the place she considered home and accepted a position as the director for the Center for Student Development/Counseling Center at the University of Memphis. During this same time, she accepted an appointment as adjunct professor in the Department of Counseling, Educational Psychology, and Research at the University of Memphis; this later turned into a full professorship. As the director of the counseling center, she had the vision to establish an internship at the university, and due to her determination and diligence as well as the commitment of others, this internship has been accredited by the Office of Program Consultation and Accreditation (OPCA) of the American Psychological Association since 1988.

During her tenure at the University of Florida and at the University of Memphis, Bingham worked with a variety of students, and she has been amazed by the impact of career counseling on these students' well-being and academic performance. Because of this, she has sustained an interest in vocational counseling and has written many journal articles and book chapters and coedited one book on the subject, particularly as it relates to multicultural career counseling. Also, several of the counseling models she codeveloped with Connie Ward (e.g., Steps to Career Counseling and Multicultural Career Counseling Checklist for Counselors) have become staples for researchers and practitioners alike when addressing career counseling issues with a wide range of individuals.

In 1993, Bingham became assistant vice president for student affairs/student development, because she wanted to continue to make a difference in the lives of University of Memphis students and to facilitate change in her community and beyond. She worked earnestly on improving the retention of undergraduate students, particularly those at risk, meaning they had either low ACT scores or low grade point averages upon entering the university. Student retention was an area that Bingham invested much time and effort in, and she established procedures to learn more about at-risk students and how to maintain their level of engagement. For instance, she developed a retention committee, she sent quarterly retention newsletters to alert faculty and administration about the concern, and she conducted studies to determine the predominant reasons for academic withdrawal and the ways in which the students felt that the administration could support them.

In 2003, after a national search, Bingham was selected as vice president for student affairs at the

University of Memphis. It was once again because of her determination and her penchant for viewing things outside the box that she was able to become the first female vice president in the history of the University of Memphis. This is not to mention that she is also the first African American female vice president in the school's history, which is quite an accomplishment given that years earlier Martin Luther King, Jr., was assassinated in the very same city because of his vision and his beliefs on equality and justice. Her mission as vice president focuses on "Students Learning through Engagement and Involvement." Her staff describes her as disciplined, excellent to work with, fair, inclusive of everyone, and having a great sense of humor.

Bingham is nationally renowned as a contributor to the discipline of psychology in numerous roles as academician, scholar, scientist, licensed practitioner, leader, and policymaker. Her vision allows her to lead effectively, and she has done so on more than one occasion as president of the Association of University and College Counseling Center Directors, president of the International Association of Counseling Services, and president of the American Psychology Association's (APA's) Society of Counseling Psychology (Division 17). As an active leader in APA, she has also chaired the Board for Professional Affairs and participated on the Ethics Committee, the task force for APA's annual convention, and the transition team for a past APA president. She is also a Council of Representatives member for Division 17, has served in various caucus capacities (e.g., Utilization of New Talent, Women's Caucus), and has been involved in bringing issues, particularly of science, into APA governance. One peer has described her as a "wonderful woman who says what she believes and has an uncanny knack for saying the difficult things that must be said but making them palatable for others to digest."

With some of the leading psychologists in the nation, Bingham cofounded and organized, in 1999, the first National Multicultural Conference and Summit, which focused on ground-breaking multicultural psychology, science, research, and practice. Because of its success, she and the other cofounders were asked to coordinate follow-up summits in 2001 and 2007. Bingham has also served on the editorial boards of *The Counseling Psychologist*, *Journal of Counseling Psychology*, *Journal of College Student Development*, and *Journal of Counseling and Development*, *In Session* for the *Journal of Clinical Psychology*, and the *Journal of Career Assessment*.

Bingham has given numerous presentations at national conventions and conferences and has been recognized in several ways as a woman with determination and vision. For instance, she was acknowledged as Woman of the Year by the Section for the Advancement of Women of the Society of Counseling Psychology and has been selected as 1 of 15 women from around the world to participate in the Women of Color Development Incubator Project funded by the Kellogg Foundation. In June 2004, Bingham also became chair of the board of the Women's Foundation for a Greater Memphis, a philanthropic organization that focuses on women's economic independence.

Rosie Phillips Bingham's life and work continue to be inspired by determination and vision. She will assuredly continue to answer the call, which she labels in her life as her response to a higher power compelling her to care and to do.

linked to bullying. Bullying has been defined in many ways, and there is some disagreement about what behaviors constitute bullying. The most widely used definition, provided by Olweus, a leading researcher, states that people are bullied when they are repeatedly exposed to negative actions from others. Olweus proposed three key components of bullying: intent to harm another person, behavior repeated over time, and imbalance in power between the bully and victim. This definition includes behaviors as diverse as physical abuse, threats of harm, teasing, social exclusion, spreading rumors, damage of property, and theft. Some believe that an imbalance of power need not be present. However, others suggest physical, psychological, or social power differences must exist to constitute bullying. Other definitions state that bullying may be conducted for the purpose of displaying dominance.

Historically, most attention has been focused on direct forms of bullying, including overt physical and verbal aggression. Direct physical bullying includes behaviors like hitting, kicking, and pushing and sexual aggression such as touching, pinching, and groping. Direct verbal bullying includes behaviors such as name calling, teasing, and threats of harm. Additional forms of bullying have been identified, including the use of intimidation; bullying based on one's race, ethnicity, culture, appearance, or ability; and sexual harassment or using sexual references to make someone uncomfortable. Often, children are both victims and perpetrators of bullying.

Recently, much attention has been given to indirect forms of bullying, which are sometimes referred to as social or relational bullying. This type of bullying is more covert in nature and often has the goal of damaging the victim's social relationships or reputation. Relational bullying includes behaviors such as spreading rumors, social exclusion, friendship manipulation, and gossiping.

### Gender Differences

Differences have been found between the ways boys and girls use and respond to bullying. Traditionally, bullying was thought to be more of a male phenomenon and that bullying was more prevalent among males. This bullying was direct in nature; it included physical assault or threat of assault. More recently, researchers have found girls to be equally involved in bullying, but they have the tendency to use more indirect means of aggression such as relational bullying. This has led to the terms *boy bullying* (referring to

---

## BULLYING

---

Bullying is a problem that threatens the well-being of children and adolescents across the world; estimates are that up to 50% of children are perpetrators or victims. Numerous school shootings recently have been

direct aggression) and *girl bullying* (indirect aggression). However, it appears that the distinction between gendered forms of bullying is more complex than previously thought. While research supports the concept that boys are involved in more direct forms of bullying than girls, recent research has found that boys and girls show equal involvement in indirect bullying, but they respond to it differently. More specifically, some researchers believe that indirect forms of bullying appear more harmful to girls than to boys.

### **Prevalence**

There appears to be a high prevalence of bullying worldwide, with general prevalence rates ranging from 11% to 50% of school children. Bullying has been assessed in numerous countries in North America, Europe, and Asia. Most countries report prevalence estimates of 10% to 20% of students being involved with bullying. The prevalence of bullying in the United States is one of the highest in the world; most estimates are that between 20% and 30% of all U.S. school children are involved. However, these rates are likely underestimates of the actual prevalence of bullying due to underreporting by students, exclusion of relational bullying, and unawareness of the extent of bullying in schools by teachers and parents. There may be prevalence differences between urban and rural areas. Recent research on bullying in small or rural schools reported much higher rates of bullying, with upwards of 80% of students reporting involvement in bullying. Bullying has been shown to begin as early as the toddler years, and it increases through middle school. Bullying behavior tends to peak during junior high and then slowly decline throughout high school.

### **Outcomes**

Bullying has been associated with a number of adverse outcomes for both the bully and the victim. More specifically, bullying has been shown to affect psychosocial well-being, academic achievement, and physical health. Some long-term outcomes have also been associated with bullying.

#### ***Victims***

Victims experience problems with depression, anxiety, low self-esteem, aggression, relationship problems, social isolation, loneliness, substance abuse, psychosomatic

symptoms, and even suicide. In terms of academics, victims of bullying exhibit school refusal behavior (contributing to frequent school absences), dislike of school, reduced participation in school activities, and lower academic achievement than nonbullied peers. Children who are frequent victims of bullying may also report more headaches, stomachaches, and other somatic complaints, which could lead to greater health-care utilization and costs. Long-term outcomes of being victimized include continued depression and anxiety as well as relationship problems.

#### ***Bullies***

Bullies exhibit many externalizing problems, including aggression, antisocial behavior, conduct problems, delinquency, substance use, and early sexual experiences. They have also been shown to experience internalizing problems, such as anxiety and depression. Some bullies experience victimization, negative reputations, and difficulties with peer relationships. Academic outcomes associated with bullies include truancy, low academic achievement, and dropping out of school. Long-term consequences of bullying may include sustained antisocial behavior, abuse, domestic violence, substance abuse, and trouble with authorities.

### **Treatment and Prevention Programs**

Numerous prevention and treatment programs have been developed to address school bullying. Overall, research has shown modest but consistently positive effects of such programs.

#### ***The Olweus Bully Program***

The Olweus Bully Program is a comprehensive, schoolwide program designed to reduce and prevent bullying problems among school children. A secondary aim of this program is to improve peer relations at school. This program can be used with children in elementary school, middle school, or junior high school. The Olweus program has been shown to be effective in reducing bullying, improving the social climate within schools, and reducing antisocial behaviors. This program has been successfully implemented in several countries around the world.

The Olweus Bully Program seeks to reduce bullying through restructuring the school environment and

intervening at three levels: the school, the classroom, and the individual. This program strives to make the school a safe learning environment for all students and to reduce the negative effects associated with being a victim and a bully. Some of the key aspects of the program include identifying bullies and victims through administration of the Olweus Bully/Victim Questionnaire, formation of a bullying prevention coordinating committee, staff training, development of schoolwide rules against bullying, supervision during break periods, regular classroom meetings about bullying and peer relations, class parent meetings, and individual work with those identified as bullies or victims and their parents. Educators are trained to work with individuals to reduce certain behaviors known to be risk factors for bullying. These risk factors include impulsivity, dominant personality, lack of empathy, difficulty following rules, low frustration tolerance, positive attitudes toward violence, and decreased interest in school. The Olweus Bully Program also seeks to intervene with students who have known risk factors, such as having friends with positive attitudes toward violence, lack of parental warmth and involvement, overly permissive parenting, harsh discipline, lack of parental supervision, and school attitudes that are indifferent to or accepting of bullying behavior. Outcome studies on this program have shown it to reduce bullying behaviors by 33% to 64%.

### ***The Steps to Respect Program***

The Steps to Respect Program is a bullying prevention program for elementary students that seeks to create a safe and respectful school climate through bullying prevention. Educators, students, and families are encouraged to reduce the problem of bullying at the schoolwide level. The main objectives of this program are to increase prosocial beliefs and behaviors, to increase personal responsibility for bullying (including the responsibility of bystanders to intervene), to understand that aggression is an unacceptable route to power, and to increase access to peers and adults for functional and emotional support.

There are three phases to this program. The first phase involves getting the school to commit to the program through developing a bullying prevention

steering team to create bullying policies and consequences for bullying behavior. The second phase involves training the staff to recognize bullying and effectively deal with its occurrence. Families are also educated about the program at this time. The third phase involves implementing the program by having educators deliver skill lessons to children, helping children learn and practice bullying prevention skills, and teaching prosocial skills. Throughout this instruction, children should learn how to recognize, refuse, and report bullying.

## CANCER MANAGEMENT

---

Managing one's experience with cancer requires coping with diagnostic procedures, treatment protocols, uncertainty in prognosis and recurrence, and often a reduced capacity to engage in normal, daily activities. These external and internal demands may seem overwhelming at times and challenge an individual's ability to cope. The term *coping* has been defined by Richard Lazarus and Susan Folkman as a person's changing cognitive and behavioral efforts to manage psychological stress resulting from a situation or event appraised as harmful in some way. This widely accepted definition emphasizes a fluid process in which coping responses change depending on one's subjective evaluation or appraisal of his or her circumstances. Individuals diagnosed with cancer commonly appraise their situation as threatening, harmful, or personally challenging, and they often experience a sense of loss and control. They and their families face practical concerns in terms of paying for medical care, time lost from work or school, and a limited ability to fulfill normal role expectations. Therefore, the goals of adaptive coping with a cancer diagnosis and treatment are most appropriately defined by the quality of life one is able to maintain on a daily basis rather than by the ultimate resolution of the cancer experience.

### Common Coping Strategies

Coping strategies are commonly categorized as either approach versus avoidance strategies or problem-focused versus emotion-focused strategies. The coping

literature indicates that in the context of an uncontrollable situation such as cancer, approach-oriented strategies such as cognitive restructuring, seeking social support, and information seeking tend to be more adaptive ways of managing one's disease than avoidant strategies like denial and disengagement. That said, because of each person's unique personal and situational attributes and the multidimensional nature of the cancer experience, researchers also conclude that there is no one right way to cope. Two seemingly similar coping responses may produce very different results or a strategy that is helpful in one context may not be helpful in another.

For example, two common, approach-oriented, emotion-focused strategies are *positive reinterpretation and growth* and *focusing on and venting of emotions*. Both involve the acknowledgment, processing, and expression of emotions. Positive reinterpretation and growth is related to adaptive outcomes and involves cognitively reprocessing distressing emotions resulting from a stressful event into a new framework that incorporates positive aspects as well; it is an individual's deliberate effort to take knowledge gained from a negative experience and use it to move forward in a positive direction. Focusing on and venting of emotions is a process of attending to and expressing typically distressing feelings. Research indicates that engaging in emotional expression may only contribute to positive adaptation when one is able to express him- or herself in the context of a receptive, supportive network of others who are willing and able to listen. In the absence of a supportive environment, this strategy may lead one to ruminate excessively, thereby compounding the stress already being experienced.

The stress and coping literature suggests that problem-focused coping strategies typically associated with managing external demands may not be effective in reducing the emotional distress generated by uncontrollable factors in situations such as facing cancer. Resolving the ambiguity inherent in living with an uncertain prognosis as well as some limitations resulting from treatment side effects are beyond one's ability to control. Taking action to resolve these types of problems is not possible, and attempting to do so may further emphasize the uncontrollable aspects of the situation and lead to more anxiety and worry. An important distinction here is the recognition that problem-focused coping doesn't necessarily imply taking action directed at the broad scope of the problem itself; it may also involve passive, approach-oriented strategies directed at consequences.

For example, managing the daily uncertainty imposed by a cancer diagnosis and treatment requires willingness to approach external demands, like complying with treatment, with a certain amount of deliberate acceptance aimed at increasing one's ability to tolerate unavoidable physical and psychological distress. Acceptance of one's situation can be the first step in taking a more active role in understanding the nature of the cancer experience. Cancer patients often report an increased sense of control and well-being when they accept responsibility and become stronger advocates for their own medical care via seeking information and instrumental support. Among men with prostate cancer, approach-oriented coping strategies were related to decreased levels of depression and anxiety, better self-esteem, and more positive mood. Conversely, prostate cancer patients who tended to manage distress through avoidance reported both poorer physical and poorer psychological health.

### **Individual Differences in the Coping Process**

While coping is generally thought of as a transactional process between an individual and the environment rather than as a stable, person-centered trait, individual differences such as personality and dispositional characteristics influence the coping strategies one tends to engage in when attempting to regulate physical, emotional, and behavioral distress. In the area of breast cancer, which has been particularly well researched, women in advanced stages of cancer who were more optimistic exhibited an ability to approach

their prognosis with a combination of realism and fighting spirit that was related to significantly lower levels of anxiety and depression than were seen in less optimistic women. Similar findings in other areas of the adult cancer literature indicate that overall, more optimistic cancer patients tend to use more approach-oriented, active, and accepting coping strategies and report less distress during each phase of cancer treatment than patients who are less optimistic.

### **The Role of Social Support**

Social support, broadly defined as having one's need to feel a sense of belonging, care, affection, and esteem met by others such as spouses, parents, friends, coworkers, and classmates, can be a valuable resource for both adult and pediatric cancer patients and their families. While differences among the types of support offered—that is, how it is offered, when, and by whom—relate to one's perception of how helpful it is, social support is generally related to better physical and psychological adjustment.

### **Coping and Positive Emotions**

The literature on adaptation to chronic illnesses, including cancer, has shifted away from measuring coping outcomes solely by an absence of distress toward also determining whether positive mental and emotional states are present. The experience of positive emotions is considered an adaptive response that may help to sustain an individual's inner resources during lengthy periods of stress, to maintain much needed social support networks, and to contribute to more optimal use of adaptive coping strategies. Research indicates that it is not at all uncommon to experience positive moods and emotions, such as benefit-finding, in the midst of simultaneous feelings of psychological distress produced by ongoing stressors. In Shelley Taylor's theory of cognitive adaptation to trauma, benefit-finding is a subjective evaluation that operates as a way to enhance and maintain one's self-esteem in a threatening, aversive situation such as cancer. Cancer patients frequently identify benefits resulting from their cancer experience, such as closer family relationships, deepening of values, and a reordering of life's priorities. Benefit-finding among cancer patients and survivors has been positively linked to better mood, stronger self-efficacy, and better social support. Increased levels of benefit-finding

have been documented in people with more advanced cancers compared to those with earlier-stage diagnoses and may help these patients maintain a balance between the positive, soothing aspects of their lives and the threatening reality of their cancer.

### **Coping With Cancer in Childhood and Adolescence**

Family, caregiver, and environmental factors, as well as a child's age and developmental stage at diagnosis and throughout treatment, play a significant role in shaping an experience very different from that of an adult cancer patient. How pediatric cancer patients and their families cope varies greatly depending on a host of situational factors. Because children may look to their families and other adults around them for cues to help them understand and manage their cancer experience, the responses of parents, caregivers, and others in their immediate environment impact their adjustment. In general, children who perceive less cancer-related stress in their environment exhibit better adjustment than those who experience more stress. Children are better able to adjust when their families are supportive, adapt positively to changing circumstances, and are able to work together. Furthermore, an open style of communication among family members seems to foster a child's ability to communicate more openly about his or her experience and is positively related to more optimal outcomes. When a child is undergoing a diagnostic or treatment procedure, parents or other caregivers are usually present. Adults' responses, including to pain, are significantly related to a child's subjective experience of these events. Children whose parents and caregivers support them with expressions of warmth, concern, and empathy during these procedures perceive significantly less pain and distress and exhibit better adaptive outcomes than children whose fears and concerns are not validated or soothed by their adult caregivers.

### **Developmental Factors**

Because of the normal growth and maturational processes simultaneously occurring in childhood and adolescence, the physical and psychosocial late effects of cancer have the potential to be more detrimental for pediatric cancer patients than for adults. Advances in neuroscience have increased our ability to understand cognitive and affective developmental

trajectories across the life span. Overall, children with higher levels of cognitive abilities typically exhibit better adjustment than children with developmentally less advanced cognitive abilities. Higher-order cognitive processes such as the ability to plan and think abstractly, to regulate emotion, and to coordinate one's cognitions and emotions do not begin to fully develop and mature until adolescence. These maturational growth processes proceed independently and at different rates for each individual.

In terms of coping with a cancer diagnosis, this means that an adolescent cancer patient may have developed the ability to perceive the serious long-term implications of his or her diagnosis but still not have the emotional maturity to cope with the ensuing distress. The interaction of these varying developmental stages has the potential to heighten an adolescent's perception of threat over and above what may be perceived by an adult with a better ability to gauge risk and cope with intense thoughts and emotions. Because cognitive and emotional processes continually factor into their ongoing appraisals of the events composing their cancer experience, their developmental stage significantly influences their coping abilities as well as strategies used. Therefore, children and adolescents face unique challenges coping with the negative emotions produced by their experience with cancer.

### ***Pediatric Physical and Psychosocial Late Effects***

Physical late effects following pediatric cancer treatment may include compromised sensory functioning; neurocognitive impairment; problems with endocrine function; damage to the kidneys, liver, and heart; and infertility. Some physical late effects, such as infertility, vary according to age and gender and may not be fully appreciated until adult roles are being assumed. As pediatric cancer patients mature, deficits in specific areas of functioning can arise, including decreased academic achievement, employment difficulties, fewer social relationships, a poorer sense of self and identity, and symptoms of posttraumatic stress.

Despite well-documented evidence of physical and psychosocial impairments, research shows that most pediatric cancer patients adapt and cope very well, and there is very little evidence of overall maladjustment. Adolescent cancer survivors typically rate

themselves significantly higher than their noncancer peers in terms of physical and emotional functioning, academic functioning, overall quality of life, and frequency of positive mental states, and they rate themselves as having fewer experiences of emotional distress. The contradictions between these objective and subjective indicators of adjustment suggest that coping strategies used by adolescent cancer survivors enable them to effectively suppress distress and view themselves in a positive light.

### Repressive Coping Style

In the larger body of psychological literature, individuals who avoid distress by blocking out or repressing negative stimuli are termed *repressors*. Repressors report a pattern of low levels of anxiety combined with high levels of defensiveness even under difficult circumstances. Adult repressors who have never experienced a cancer diagnosis often exhibit increased levels of stress-related health problems, including high blood pressure, ulcers, migraines, and irritable bowel syndrome. Some children with cancer may adopt a *repressive adaptive coping strategy* whereby they minimize the distressing aspects of their disease.

Research shows that repressive coping among both adult and pediatric cancer patients arises as an adaptive response to a seriously threatening event. It has been related to significantly decreased levels of depression in pediatric patients, especially among adolescents in the active treatment phase. As an adaptive strategy, it is sustained across time as children struggle to cope with and manage levels of distress for which they are developmentally ill prepared. However, extant research on adolescent patients with cancer shows increased rates of repressive coping persisting as long as 12 months after diagnosis compared to just 12 weeks in adults with cancer. Repressive coping strategies that become habitual and long-term in pediatric cancer patients raise additional concerns regarding their future well-being in light of the poor health outcomes seen among adult repressors. When, how, and if repressive coping strategies subside among pediatric cancer patients as the length of their cancer survival time increases are questions that remain unanswered.

## CAREGIVER BURDEN

---

*Caregiver burden* is a term used to describe the physical, mental, social, and financial impact of caring for someone who is ill or who has functional impairments. Although the term can be applied to all caregivers (paid and unpaid), in most circumstances the term is applied to unpaid caregivers (called *informal caregivers*) who are usually family members of the ill or impaired care receiver.

### Description of the Caregivers and Care Receivers

A large national study of informal (unpaid) caregivers and care receivers in the United States (conducted in 1999) found that two fifths of caregivers fall between the ages of 45 and 64, one fifth are aged 65 to 74, and another one fifth are over the age of 75. Thus, a significant number of caregivers are older adults, themselves at risk for health problems due to advanced age. The same study found that two thirds of all caregivers are female, and most informal caregivers are immediate family members of the person needing care. Around 40% are spouses, another 40% are adult children, and the remaining 20% are categorized as “other” and can include friends, neighbors, siblings, grandchildren, or other relations. Although the number of hours spent providing care can vary from person to person depending on the level of dependency of the care receiver, the National Alliance for Caregiving reports that 17% of caregivers provide care for more than 40 hours per week. Therefore a significant number of caregivers are providing care full time for their relatives. In addition, many are providing care on their own, without the help of secondary caregivers. In 1989, about one third of caregivers reported being the only caregiver for their relative. Over the next ten years, however, this number rose dramatically. In 1999, around half of all caregivers reported providing care on their own, without the assistance of others.

Care receivers can vary significantly in their ages, their level of impairment, and their reasons for needing care. Most research on caregiver burden evaluates

caregivers of people over the age of 65 who are living in the community (not in nursing homes or other care facilities), but of course people can need care at any age. Care receivers typically need assistance from caregivers in instrumental activities of daily living (IADL), which include assistance with activities such as shopping, transportation, and household chores. Sometimes care receivers are impaired even further, needing assistance in personal activities of daily living (PADL), which include needing help with bathing, eating, dressing, or other personal care needs.

Much of the research on caregiver burden studies caregivers of people with dementia, particularly those with Alzheimer’s disease. For these caregivers, in addition to providing assistance with daily needs and activities, the caregiver also must manage the care receiver’s behavioral symptoms, such as wandering, aggression, anxiety, and depression. Research on caregiver burden is not limited to caregivers of people with dementia, however, and significant attention has been paid to caregivers of people with Parkinson’s disease, cancer, mental illness, intellectual disabilities, severe arthritis, or amyotrophic lateral sclerosis (ALS, or Lou Gehrig’s disease) and to caregivers of people who have had a stroke or who have suffered from posttraumatic stress disorder or head injury. Depending on the disease or condition, care receivers may need extended periods of time for their care. Cancer, for example, may require shorter periods of care (months), but even individuals who develop Alzheimer’s disease late in life may require 3 to 15 years of care. Caregiver burden is usually studied within the context of caregivers providing care for long periods of time, such as over months or years. Although caring for a person during an acute illness (perhaps caring for someone for days or a few weeks) may lead to feelings of caregiver burden, caregivers of this sort are usually not the focus of research on caregiver burden.

### Burden as a Predictor or as an Outcome

Caregiver burden is considered to be an outcome of caregiving, in itself, and it is also used to predict other outcomes. For example, as an outcome of caregiving, some studies have shown that increasing levels of necessary assistance (in their daily activities) for care receivers predict higher levels of caregiver burden. Caring for someone with lower cognitive functioning and caring for someone with increased behavioral

problems (for example, wandering and aggression in patients with Alzheimer's disease) has also predicted higher levels of burden. Contextual variables, such as caregivers' gender, age, and employment status, have been tested, and although findings are sometimes mixed for these variables, there is evidence that female caregivers report more burden, older caregivers report more burden, and employed caregivers report more burden.

In addition, in studies where burden is considered an outcome, certain mediator variables have been identified. For example, higher levels of quality social support from family and friends seem to buffer the negative impact of some of the above mentioned predictor variables on caregivers' levels of burden, as does getting a break from their role of caregiving. Using in-home respite services and having the care receiver attend adult day care services, for example, both seem to buffer caregivers' levels of reported burden.

As stated previously, caregiver burden is not always considered to be an outcome to be studied. It is also often used to predict other caregiver outcomes. Higher levels of caregiver burden predict a higher likelihood of placing the care receiver in an adult day care facility, and also predict higher likelihood of placing the care receiver in a residential care facility, such as a nursing home. Higher levels of burden have also been linked to higher levels of physical and mental health outcomes in caregivers; for example, higher burden has been found to predict more depressive symptoms and poorer self-rated health in caregivers.

### Objective Versus Subjective Caregiver Burden

Research on caregiver burden has differentiated between two main types of burden: objective burden and subjective burden. Objective burden refers to the physical, psychological, social, and financial impact on the caregiver caused by tangible caregiver-related disruptions to his or her life. Examples of such disruptions may include the increased amount of time the caregiver takes from his or her own life to care for the care receiver, or it may be the amount of money spent giving care. The accumulation of objective stressors, such as lack of time and lack of money, produces objective burden on a caregiver. Subjective burden, on the other hand, refers to the physical, psychological, social, and financial impact on the caregiver caused by feelings and appraisals of the caregiving role.

Some caregivers may perceive the objective tasks of caregiving as being rewarding, while others may perceive them to be quite stressful and negative. The accumulation of subjective stressors, such as negative feelings toward their role or feelings of guilt about not meeting the needs of their care receiver, produces subjective burden on the caregiver.

Although objective and subjective burdens are related to each other, many studies have found evidence that the hours spent caregiving or progression of memory loss in the care receiver (both measures of objective burden) are not related to how burdened the caregivers perceive themselves to be (subjective burden). For example, two caregivers may both be caring for a person with dementia full time (40 hours a week), and both may be exposed to similar behavioral problems and may need to perform similar kinds of care for their relative, yet one caregiver may perceive himself as very burdened by the caregiving role, while the other perceives little burden. It is thought that there is much variability in how caregivers process the stress faced from their caregiving role, and how they cope with it, which leads to such variability in the outcome of burden.

### How Is Caregiver Burden Measured?

Caregiver burden is most commonly measured by asking caregivers to fill out or respond to a multi-item scale. Several analyses have been performed to assess the number and quality of measures of burden. One such study conducted in 2004 identified 16 different measures of burden. The most widely cited measure is the Zarit Burden Interview (sometimes also called the Burden Scale, the Burden Index, or the Caregiver Burden Index). The scale, developed in 1980, was intended for use with caregivers of persons with dementia, but it has also been used with success in other contexts. Although it originally had 29 items, the 22-item shorter version is more commonly used. This scale lists symptoms or feelings related to caregiver burden, and it asks caregivers to respond with how often they feel that way, using *never* (0), *rarely* (1), *sometimes* (2), *quite frequently* (3), or *nearly always* (4). Sample items include the following: "Do you feel that because of the time you spend with your relative you don't have enough time for yourself?" "Do you feel your social life has suffered because you are caring for your relative?" and "Do you wish you could leave the care of your relative to someone else?" Caregivers' scores are added up for all 22 items, thus

the scale ranges from 0 to 88, with higher scores indicating that the caregiver feels more burden.

The second most commonly cited measure of burden is the Caregiver Strain Index, or CSI. It was first published in 1983, and it was intended for caregivers of patients who were recently hospitalized for hip fracture or heart disease. This scale has also been used with success in other contexts. The CSI is a 13-item scale with questions requiring a *yes* (1), or *no* (0) response. The responses are added for a total range of 0 to 13, with higher scores indicating higher levels of burden. In the CSI, caregivers are given a list of things that they may find difficult, and they are asked if the items apply to their caregiving experience. Sample items include the following: “There have been work adjustments,” “There have been family adjustments,” and “Some behavior is upsetting.” In addition, there has been a modified version of the scale (called the Modified Caregiver Strain Index, or MCSI) which asks similar versions of the same 13 items, but asks caregivers to respond *no* (0), *yes, sometimes* (1), and *yes, on a regular basis* (2), instead of using the original dichotomous response choice (no vs. yes). In the modified version of the scale, the responses are also summed, such that higher scores still indicate higher levels of burden.

Both the Zarit Burden Interview and the Caregiver Strain Index have demonstrated acceptable psychometric properties, with both having satisfactory levels of reliability and validity across multiple studies. Reviews of the other measures of caregiver burden have found that in general, the other scales are also acceptable, and no one scale can be deemed superior over all others. The main disadvantage of having so many measures of caregiver burden is the difficulty of making comparisons across studies that use differing measures of the construct.

### **Is Caregiver Burden a Distinct Concept?**

There is some debate over whether caregiver burden and caregiver well-being are “opposite sides of the same coin,” or whether they should be treated as distinct concepts and measured separately. Those that do not favor separating the constructs suggest that caregiver burden is merely a dimension of well-being, with both constructs measured by assessing physical, mental, social, and financial problems (or lack of problems, as is the case when measuring well-being). These researchers propose that studying well-being in

caregivers instead of studying burden offers researchers the ability to compare caregiver and non-caregiver populations. Many other researchers, however, interpret caregiver burden as a concept that is distinct from caregiver well-being (although they recognize that the two are often related to each other). Researchers from this orientation state that although caregivers high on burden are often low on well-being, there are also caregivers who have high levels of burden, but who also have adequate or high levels of well-being. Thus, it is possible for the two constructs to operate independently.

### **Interventions to Reduce Caregiver Burden**

Reducing the negative effects of stress for caregivers has often been the target of caregiver interventions. The outcome variables of interest in these studies may differ, but the studies usually aim to increase positive affect, quality of life, or health and well-being; or to reduce stress, depression, or caregiver burden. Thus, reducing burden, itself, is not always the main or only goal of caregiver interventions, but burden is often an important component included in evaluations of caregiver programs. Caregivers who are the most at risk for adverse outcomes, and who are thereby most in need of intervention, tend to be older females with little income or education who provide high levels of care, have low levels of social support, and feel they have no choice in taking on their role as a caregiver.

Interventions that aim to reduce burden in caregivers often include one or more of the following components. They may seek to reduce the needs or the behavior problems in the care receiver, or they may introduce respite care for the care receiver, thereby reducing the objective stress on the caregiver. They also may seek to target the caregivers themselves. Some interventions aim to increase caregivers’ knowledge of resources and appropriate care techniques (for example, by providing education about the availability of local services to education on how to bathe an uncooperative care receiver). Other caregiver-targeted interventions aim to provide individual (or group) support or therapy.

While providing caregivers emotional support (listening, giving advice, and reassuring them) in an individual or group counseling session may be helpful, the most beneficial aspects of counseling seem to be when there is a focus on increasing problem-solving strategies and support-seeking behaviors for the caregiver.

In general, individual treatment seems to be more beneficial for caregivers than group sessions; however, group sessions have the advantage of being less expensive (often free) for caregivers. It is important to note that referrals to psychiatrists are recommended for any caregivers displaying evidence of psychopathology, such as significant depressive symptoms.

In general, interventions that include more than one component, for example, targeting the behaviors of the care receiver as well as providing education and support for the caregiver, have more positive results. In addition, it is not surprising that higher-intensity interventions have more of an impact on caregivers than low-intensity programs. Overall, however, findings on the effectiveness of all types of caregiver interventions in reducing caregiver burden have been mixed. Some researchers speculate that this variability in the interventions' effectiveness stems from the fact that caregivers' situations, needs, and appraisals of stress vary significantly themselves. A one-intervention-fits-all approach does not seem promising in reducing caregiver burden. Although they may be more difficult to evaluate, interventions that place an emphasis on the individual needs of the caregivers may have the most effect in ultimately reducing their objective and subjective burden. It is suggested that an evaluation of caregivers' needs should include an assessment of their safety and that of their care receivers as well as an assessment of the care receivers' physical health, depression, and anxiety. Appropriate ways to intervene for the individual can then be dictated by their needs in these areas.

## CAREGIVING

---

It has been estimated that nearly 50 million people in the United States are acknowledged caregivers and that as many as one in four individuals will be involved in caregiving duties at some point in their adult lives. Given the often cited “Graying of America” phenomenon, the number of caregivers will likely increase during the coming decades.

Of significance for counseling psychologists is the fact that caregiving has been found to be associated with substantial stress and mental health problems, both of which are significant public health concerns that are amenable to counseling interventions. This entry elucidates the following: (a) a definition of caregiving, (b) its association with mental health problems, (c) strategies for coping, and (d) an approach to caregiving that emphasizes positive functioning and possibilities for skill-based strategies to assist caregivers.

### Defining Caregiving

Informal caregiving in its most elemental form characterizes a family member, loved one, neighbor, or significant other who provides direct assistance to a person (a care recipient) who, due to disability, is unable to be functionally independent without such assistance. Although the preceding definition is broad, a truly generalized characterization of caregiving is

challenging in our multicultural society. This is due primarily to the fact that the manifestations of caregiving differ across cultures and cohort groups. For instance, in some traditional cultures (Asian, Hispanic, New Zealand Maori) it is expected and even common to provide care for family members by taking them into one's home and providing the necessary instrumental and emotional support to help them maintain functional independence. In contemporary American society (particularly among the White affluent majority culture in the United States), it is less expected that a family member will serve as the sole full-time caregiver, perhaps due to current mobility trends and an increased focus on individual goals and attainments. There are also numerous ways with which people from different contexts provide care. For instance, research has demonstrated that African Americans are more likely to provide care to friends and extended family members, in contrast to White Americans who are more likely to care for a member of their immediate family. These findings suggest that like many social phenomena, defining the nature of caregiving depends to a large extent on contextual factors.

There are, however, some common elements of the caregiver experience that can help to portray, in general, the caretaker role. Caregiving is most often an activity that focuses on providing needed support to another individual who is disabled to the extent that he or she is not capable of independent functioning. Caregiving also includes providing a variety of different types of support, but more often than not includes providing direct care in the service of everyday needs that the care recipient is not capable of performing due to a disease process, an injury, or a life-long disability. With regard to the elderly, the most common problems that result in the need for caregiving stem from senile dementia (Alzheimer's disease and vascular dementia), stroke, and disorders such as severe arthritis or osteoporosis that markedly limit functional independence. Among children, pervasive developmental disorders such as autism or Rett's disorder and forms of severe intellectual disability such as Down's syndrome or fetal alcohol syndrome frequently require a family member to engage in caretaking.

### **Coping With Caregiving**

Caregiving for a significantly disabled individual is arguably one of the more difficult activities that a person undertakes during his or her life span, and it has

been shown to have a number of adverse outcomes, including depression, anxiety, and chronic physical health problems. It is likely that the distressing correlates of caregiving, known in the literature as caregiver burden, stem from a number of factors. These might include an often unexpected life change; financial difficulties; a limited amount of time for personal activities such as recreation, exercise, and intimate relationships; and, in some cases, the necessity of ceasing career pursuits due to the competing demands of the caregiver role. In the case of disorders that result in personality change of the care recipient or a progressive loss of cognitive functioning, there is often a corresponding sense of interpersonal loss on the part of the caregiver. Research has identified a number of caregiving variables that are reliably associated with negative outcomes, including problematic behavior of the care recipient and caregiver overload.

Research during the past decade has expanded the knowledge base of caregiver well-being by examining variables that are predictive of mental health outcomes. Most of this research has focused on ways of coping with the stressors of the caregiver role and has identified ways of coping that are reliably associated with negative outcomes. In particular, "emotion-focused" coping strategies, such as escape or avoidance, wishful thinking, and fantasizing have been shown to be associated with high levels of anxiety and depression. These studies have underscored the notion that coping strategies that are based on denial or avoidance tend to result in poor psychological outcomes for caregivers. It's likely that this type of coping inhibits the caregiver from facing stressors, which reduces the chance of working through the difficult issues the caregiving situation creates. Avoidant coping may also result in reduced health functioning for the care recipient, as this form of coping likely renders the caregiver less psychologically available to the care recipient.

Fortunately, current research not only has examined factors associated with negative mental health outcomes among caregivers but also has widened its lens to examine factors related to positive outcomes. This trend has been influenced by dissatisfaction of professionals in the field with the search for cures to negative mental health outcomes. There is also a growing body of literature that indicates that positive mood can serve to protect individuals from the effects of stressful experiences. Not surprisingly, research has indicated that approach-related coping strategies, such as having a problem-solving orientation, using positive appraisal,

and having a high degree of perceived control, are related to enhanced levels of positive mood among caregivers. These results indicate that strategies that enable the caregiver to approach and productively engage in active solution-focused behaviors tend to report better subjective well-being, both during the caregiving experience and after it has ended.

### A Positive Approach to Counseling Caregivers

The future trend in research appears to be moving away from strategies designed to ameliorate negative effects and consequences of caregiving in favor of a viewpoint that focuses on building a positive schema for caregiving. For instance, research with caregivers of dementia patients has indicated that providing care for a loved one can result in a sense of being personally fulfilled and a sense that one is engaged in a meaningful duty. Recent studies have also documented that certain personal characteristics such as an orientation to helping others is related to enhanced well-being among caregivers, even with the influence of other coping strategies controlled.

Robert Hill describes a “positive aging” approach to caregiving that construes the provision of care as a life skill not unlike those associated with parenting very young children. Specifically, these skills include (1) *control*, which involves the degree to which the caregiver feels able to manage the task, (2) *competence*, which relates to the caregiver’s perceived self-efficacy to perform caregiving tasks, (3) *flexibility*, which involves the ability to take a larger perspective outside of one’s immediate world purview, (4) *a positive orientation*, which involves finding meaning in the caregiver role, (5) *self-care*, or the ability of the caregiver to attend to her or his personal needs, and (6) *resource utilization*, or the extent to which the caregiver can access external sources of support to deal with issues of caregiving. When the focus of caregiving emphasizes these component skills, then the ability of caregivers to provide not only the assistance needed by care recipients but also to generate their own positive source of meaning is amplified. As a direct outcome of skill mastery, caregivers who can sustain relationship continuity through the provision of caring tend to have better long-term adjustment.

Recent research in informal caregiving has focused on finding ways to identify the benefits or positive outcomes of caring for a disabled loved one.

A contemporary instrument in the scientific literature that emphasizes this approach is the Positive Aspects of Caregiving Scale. This instrument gauges the extent to which a person finds meaning in caregiving along a number of positive dimensions, including sense of usefulness, self-esteem, relationship enhancement, meaning through service to a loved one in need, and a positive attitude toward life even in the presence of caregiving. This scale, as well as other assessment tools and intervention strategies, are the basis of the positive aging approach to caregiving. Such an approach is consistent with the long-standing traditions in counseling and counseling psychology that have emphasized individual strengths and positive coping as variables that facilitate adaptation to challenging life contexts such as caregiving. It is anticipated that a positive aging approach to caregiving will embody the design of therapeutic interventions to improve quality of life among caregivers.

## CHILD MALTREATMENT

---

*Child maltreatment* is a broad term encompassing child neglect and abuse. It has been identified at the national and international levels as a tragedy of drastic proportions, drastic in the number of people it affects and drastic in the costs it exacts from the individual, the family, and society. Concern about the problem of child abuse in the past century has grown out of two important social phenomena: the development of a specialized group of medical and mental health care professionals, educational specialists, and

legal professionals concerned with children and families, and the women's rights movement. Together, both have contributed to a social and political environment that has changed our view of children and how to work on their behalf.

## Incidence

In 2004, child protective agencies investigated approximately 3,503,000 children for maltreatment. Nearly 872,000 of these reports were substantiated. The majority of these children experienced neglect (62.4%), followed by physical abuse (17.5%), sexual abuse (9.7%), psychological abuse (7%), and medical neglect (2.1%). There is often overlap in these cases: For example, most children who are physically abused also experience neglect. In addition, 14.5% of victims experienced abandonment, threats of harm, or congenital drug addiction. Children under the age of 4 were most vulnerable for severe injury or death: 81% of the 1,490 children who died of maltreatment in 2004 were in this age group.

Approximately 54% of all victims in 2004 were Caucasian, followed by African American (25.2%) and Hispanic children (17%). African American, Pacific Islander, and American Indian or Alaska Native children had the highest rates of victimization at 19.9, 17.6, and 15.5, respectively, per 1,000 children of their own race. Caucasian, Hispanic, and Asian children had rates of approximately 10.7, 10.4, and 2.9, respectively, per 1,000 children of their own race.

## Definitions

Generally, child maltreatment is differentiated into acts of omission and acts of commission, with the former describing neglect and the latter abuse. *Neglect* is the failure to provide for a child's basic needs and includes physical, emotional, medical, mental health, and educational neglect. Examples include parents or caretakers failing to provide adequate food, clothing, shelter, or supervision; refusal to seek or delay in seeking medical or mental health care that has been prescribed or highly recommended; abandonment; permission to engage in chronic truancy; inattention to special educational needs; domestic abuse in the child's presence; or permission for the child to abuse drugs or alcohol. It is important to distinguish between willful neglect and failure to provide caused by poverty. It is also critical to consider cultural norms

and for professionals to develop cultural competence when working with families.

*Abuse* includes an injury done to a child or acts that could cause physical injury. Abuse can be psychological, physical, and sexual, although these commonly overlap: A child who is sexually abused is often physically and psychologically abused as well.

The term *psychological maltreatment* is a broader term than *emotional abuse*. It includes behaviors that could cause serious behavioral, cognitive, and emotional disorders. Examples include spurning, terrorizing, isolating, exploiting, and denying emotional responsiveness to a child. Behaviors might include constant belittling and rejecting of a child, or bizarre forms of punishment, such as locking a child in a closet.

Physical abuse consists of nonaccidental injury that is often characterized by punching, beating, kicking, biting, burning, or otherwise physically harming a child. Injury may result from discipline that is inappropriate to the child's age, but it is abuse, nonetheless.

Sexual abuse, or the more broadly encompassing term *sexual exploitation*, includes molestation, fondling a child's genitals, intercourse, sodomy, exhibitionism, incest, prostitution, and exposure to or involvement in the production of pornography.

## Signs and Symptoms

It is difficult to identify specific symptoms for specific types of abuse, as many children experience multiple types of abuse. Age, severity, and duration of abuse are also factors in how symptoms are manifested. For example, babies who are shaken (shaken baby syndrome) may experience vomiting, respiratory distress, seizures, concussion, and death. However, general indicators of child maltreatment include a sudden change in behavior or school performance, untreated medical problems, learning problems or difficulty concentrating that cannot be attributed to specific psychological or physical problems, hypervigilance, lack of adult supervision, or overly compliant or withdrawn behaviors. These children may come to school activities early or stay late and sometimes do not want to go home.

In terms of symptoms specific to abuse type, indicators of neglect may include small physical size for age, dirty or inadequate clothing, poor hygiene, malnutrition, begging, lack of medical care, failure to thrive, poor school attendance and academic functioning, and disruptive behavior. In contrast, children who are physically abused often have unexplained burns, bruises,

broken bones, or black eyes. These frequently appear after an absence from school or day care. The child may express fear at the approach of adults or may appear frightened of the parents or caregivers. Children who are sexually abused may experience nightmares or bed-wetting, show a sudden change in appetite, express bizarre or unusual sexual knowledge for the child's age, have difficulty with walking or sitting, may run away, and may refuse to participate in physical activities.

## Historical Perspective

Recent statistics may give the appearance that child abuse is increasing. However, gathering statistics on child maltreatment is a recent practice, so it is difficult to be certain if there is more abuse now than in ancient times or earlier in the last century. It is important to think about how children are viewed as we try to understand abuse through history. In modern times, children are often seen as having inherent worth and deserving of protection, but it has not always been this way. There is evidence of child welfare from ancient Mesopotamia, 6000 years ago, when orphans had their own patron goddess. According to the *Regveda*, one of the oldest sacred Hindu texts, a deity among the ancient Hindus looked after abandoned children. More than 4,000 years ago, there were laws pertaining to child abuse from the Code of Hammurabi, king of Babylon. However, in ancient times and in some cultures, until the right to life was bestowed, the infant was a nonentity who could be disposed of. A father had to acknowledge a child and he had ultimate authority over the child and over the mother.

In 17th- and 18th-century Europe, children might be seen as property belonging to the father, as low-wage workers, or as "blank slates," or innocents, worthy of care. Children are often depicted as miniature adults in artwork from this time. European writers wrote treatises urging parents to adopt nonviolent childrearing methods, as children were commonly beaten and sometimes killed. The character Cosette in Victor Hugo's *Les Misérables* was used as a metaphor to admonish French society for its severe punishment of children and its lack of concern for abandoned children. Johann Peter Frank, the founder of the public health field, advocated for child labor laws in the 18th century, but it took 100 years before such laws were developed and enacted.

Developments in the 19th century include the first commissioned study on abuse, in 1860, from France, to determine why some parents kill their children. In

1866, the Society for the Prevention of Cruelty to Animals was established. The case of “Mary Ellen” is well known in the child maltreatment field. Mary Ellen was a severely abused little girl, and there were no laws to protect her. Her protection was ultimately undertaken through the New York Society for the Prevention of Cruelty to Animals, which was established prior to the Society for the Prevention of Cruelty to Children. In 1876 these two organizations joined together to form the American Humane Association.

In the 20th century many changes were designed to benefit children. One of these changes was compulsory school for both genders. Prior to the 20th century, girls often stayed home, where there was more opportunity for abuse as they had little exposure to the public. Child labor laws were enacted during the industrial revolution, and laws were developed against harsh physical punishment. Very important, the development of child welfare agencies spread. In 1961, Henry Kempe, a Denver pediatrician, and his colleagues developed the model for child abuse law that has since been adopted throughout the United States.

In 1974, the Child Abuse Prevention and Treatment Act (CAPTA) was passed, and the National Clearinghouse on Child Abuse and Neglect (NCCAN) was established. In 1978, child sexual abuse was incorporated into the federal law, expanding the scope of mandatory reporting requirements. In 1978, the Indian Child Welfare Act became law. This law was designed to keep Indian children more closely connected to their families, or to other tribal members in the cases of necessary adoptions. The 1984 publication of the American Humane Association’s book *Making an Issue of Child Abuse: Political Agenda Setting for Social Problems* was influential in making child abuse an important political agenda item. In 1993 the United Nations adopted the resolution on the Rights of Children.

Clearly there have been improvements over time as views of children have changed and laws have been enacted for their protection. Organizations abound to provide education to parents and caregivers. Nevertheless the problem of child maltreatment persists, and it is important to have some understanding of the circumstances and dynamics that lead to it.

## Causes

There is a considerable body of research examining why maltreatment occurs in the most vulnerable of

our population: children. Most recent research suggests that models studying interactive processes taking multiple variables into account will be the most fruitful for understanding the causes of child maltreatment. Although models vary, all consider at least three common dynamics that interact together: the parent (or caretaker), the child, and the environment.

## Parents

The vast majority of child maltreatment occurs within the family. Certain parental factors are significant predictors of maltreatment. These may include depression, lack of impulse control (especially when stressed), excessively high and developmentally inappropriate expectations of the child, lack of empathy, or an impaired attachment with the child. Parents may themselves have a history of victimization as a child, but most abused children do not become abusive parents. Those who do become abusive often have unresolved issues regarding intimacy, trust, autonomy, and dependency. Other risk factors for parents include young age, being a single or nonbiological parent, lack of knowledge about childrearing, a chaotic lifestyle, and low frustration tolerance. Lack of social support is a very significant finding in research examining child maltreatment potential. Parents’ reluctance to admit they need help, and their lack of knowledge about how to ask for or access help, is also critical. We live in a culture that emphasizes independence and autonomy. Asking for help may be perceived as a weakness. If a parent at risk is not part of a cohesive community, his or her increased isolation contributes to a sense of estrangement that further exacerbates stress.

## The Child

It is important to understand the bidirectionality of the parent–child relationship, as each party fundamentally influences the behavior of the other. The following types of children are overrepresented in maltreatment situations: normal infants who were unwanted or are the product of an untimely pregnancy, children with disabilities, “difficult” children (that is, those who are difficult to soothe, feed, or take care of in other ways), and adopted or foster children. Certain child characteristics (e.g., behavior problems such as hyperactivity, irritability) may also increase the risk of maltreatment.

## The Environment

This term refers to the immediate and personal environment as well as the broader cultural environment. Stressors associated with the more immediate environment include economic problems, unemployment, chaos, violence between parents, overcrowding, and isolation. Within the broader cultural environment, certain attitudes, beliefs, and practices of the culture can contribute to an environment ignorant or tolerant of maltreatment. These include an emphasis on individual rights, male supremacy or aggression, tolerance for abuse, and isolation from family and community.

## Consequences

Not all children who suffer maltreatment exhibit significant effects as a result of their maltreatment. Personal characteristics such as optimism, high cognitive ability, high self-esteem, or a sense of hopefulness in spite of the circumstances may function as a buffer to the potentially damaging effects. Other children experience a wide range of cognitive, emotional, psychological, behavioral, and relational consequences of child maltreatment. These effects are determined by factors such as age, type, severity, and chronicity of abuse.

Maltreatment during infancy and early childhood may restrict healthy brain development. For example, insufficient nutrition and emotional stimulation can have an impact on the release of important growth-regulating hormones. This affects the physical development of both the body and the brain, which can lead to severe and irreversible damage. Without remedial interventions, developmental damage in these early stages may result in deficits that follow the child into later developmental stages, producing a variety of problems. Long-term consequences of shaken baby syndrome can include blindness, mental retardation, learning disabilities, paralysis, and cerebral palsy.

In general, child maltreatment has been linked to the development of internalizing disorders such as depression, anxiety, somatic complaints, suicidal intention, and posttraumatic stress. It is also linked to externalizing disorders such as acting out, aggression, eating disorders, impulsivity, anger, delinquency, hyperactivity, attachment disorder, sexual acting out, and cognitive impairments or delays. Physically abused children tend to be aggressive toward peers and adults and to have difficulty with empathy and

establishing relationships with others. Neglected toddlers may have difficulty trusting others. This may lead them to feel unloved and unwanted and may inhibit their ability to learn the social skills they need to develop lasting and meaningful relationships, thus becoming a lifelong problem. Adult survivors of childhood maltreatment are 3 times more likely than other adults to suffer mood disorders and 2 to 4 times more likely to suffer from an anxiety disorder.

Like physical abuse, the consequences specific to sexual abuse vary by age, severity, and chronicity of abuse and number and relationship of perpetrator(s). Research indicates that symptoms vary over time, and some symptoms may be more transient than others. Not all sexually abused children experience these adverse effects. Approximately one third of victims show no clinical symptoms. The most common symptoms identified in preschoolers are anxiety, nightmares, posttraumatic stress disorder, inappropriate sexual behavior, and internalizing and externalizing behaviors. Somatic problems include enuresis, stomachaches, headaches, and developmental delays.

School-age children may display fear, aggression, nightmares, school problems, hyperactivity, and regressive behavior. Like the preschoolers, they may exhibit inappropriate sexual behaviors. They may also experience dissociation and difficulties with peer relationships. In the academic domain, they may receive poor performance ratings from teachers and have low achievement test scores, and they frequently receive diagnoses of attention deficit hyperactivity disorder (AD/HD). Adolescents may exhibit depression, withdrawal, somatic complaints, running away, eating disorders, substance abuse, suicidal or self-injurious behaviors, and delinquent behaviors. In adulthood, survivors may abuse alcohol or drugs and may experience externalizing problems such as diagnoses of antisocial personality disorder. They also may experience depression and anxiety, greater revictimization rates, and problems with child rearing.

In addition to individual effects, child maltreatment affects families and society. A 2001 report by Prevent Child Abuse America estimates the cost of health system, judicial, and law enforcement responses at \$24 billion a year. In addition, there are also indirect costs associated with maltreatment, such as the cost of providing special education services for affected children and providing treatment for mental illness, substance abuse, domestic violence, and juvenile and

adult criminal activity. These indirect costs may cost more than \$69 billion per year.

## Cultural Considerations

Lisa Aronson Fontes, an expert on multicultural counseling and child abuse, emphasizes the importance of taking an ecosystemic perspective for understanding child maltreatment. This includes examining all relevant social worlds the child inhabits. Professionals need to consider the individual—including the child's genetic makeup, developmental status, and home and family situation; the ethnic culture—including gender roles, religion, and worldview; the proximal social system—including school, neighborhood, and peer group; and the wider social system—state and national policies that impact all other systems. If counseling professionals are too close to the individual perspective, they may miss contextual variables that could assist them in helping a person. Conversely, if they have too wide a lens, they may miss important cultural variables, such as native child-rearing practices important for appreciating the child in his or her context.

This ecological model is useful in three ways: (1) It deemphasizes the individual, who is otherwise the focus in much of Western culture, (2) it indicates various levels where professionals can intervene for the child, and (3) it shows professionals where they fit in the child's ecosystem. If they are not from the same culture, they are one step further away; they need to have culture-specific knowledge to get closer. Professionals can also see how they are influenced by the proximal and wider social systems. It is critical to be aware of their own professional ethnocentrism, that is, to understand how the culture of their profession influences how they see the world. This requires them to be conscious of their own biases, to confront stereotypes, and to have culturally relevant information. This information should include knowledge of how child maltreatment is defined and of traditional help-seeking behaviors, including unfamiliar disciplinary methods and medical interventions. They must also consider issues of language and the appropriate use of interpreters. With low-income clients, professionals need to be aware of the influence of poverty in their clients' lives and recognize that what may look like neglect may be related to poverty.

Writers in the child advocacy and multicultural counseling fields emphasize that professionals need to

work within a systems framework. For example, they need to ask how nonabusive family members can help. Fontes notes that the main predictor of success for recovery from incest is the mother believing the disclosure. A few guidelines for working with families include knowing who is considered "family"; it may include godparents and close friends who are not related by blood. Professionals should understand family structure, gender roles, and respectful ways of addressing clients. Families often appreciate mental health professionals who help them access community and social resources other than counseling.

## Counseling Interventions

Early interventions are necessary to reduce the severity and chronicity of abuse symptoms and alter family and environmental factors contributing to maltreatment. Services and interventions for maltreatment should be multidimensional, including individual, family, and societal interventions. Research studies on intervention effectiveness indicated that individual, group, family, milieu, or multilevel forms of treatment are equally effective. Surprisingly, treatment effects did not vary based on voluntary versus mandated treatment.

Individual interventions may include providing appropriate medical care, helping the child express his or her emotional experiences (verbally or through drawing or play), processing trauma or neglect, reducing or overcoming general feelings of shame resulting from maltreatment, finding educational services to improve cognitive ability and academic performance, and teaching personal safety skills, empathy, assertiveness, and relationship-building skills appropriate to the child's age.

Since nearly 84% of victims of maltreatment are abused by a parent, family interventions should address issues such as improving parenting skills. This can include education on nonviolent discipline strategies, child developmental stages, effects of maltreatment, anger management, and communication skills. Interventions should also assess and address family mental health or substance abuse issues contributing to family dysfunction and explore gender roles that may contribute to abuse.

In a broad general sense, the treatment process consists of three phases: (1) acknowledgment of the abuse and its subsequent effects, (2) development of parenting competencies and sensitivity to the child, and

(3) resolution either through reunification of the child with the family or relinquishment of parental rights.

Individuals involved in providing support and assistance to children and families involved in maltreatment often include nurses, doctors, teachers, school counselors, social services staff, therapists, foster care providers, law enforcement officers, and individuals in the judicial system. However, while these services focus on the protection of children and punishment of abusers, they rarely provide assistance in addressing the unemployment, poverty, and substance abuse that frequently play a role in child maltreatment. These issues need to be addressed at the societal level to effectively combat child maltreatment. Similarly, non-English-speaking minority families may feel isolated from community services that could help them cope with financial, cultural, and familial stressors. Federal and local governments and communities need to provide services for these families to prevent them from having to enter the child protection and legal systems.

Finally, a significant and badly needed intervention in maltreatment is developing effective prevention programs. Primary prevention interventions begin with raising the awareness of the public and decision makers about maltreatment. These include public service announcements regarding available programs and services, school safety programs, free parent education programs, and information on how and when to report abuse.

## CHILDREN WITH CHRONIC ILLNESS

---

Approximately 20% of school-age children have a chronic illness, making counseling increasingly important due to the impact on the child's family relationships, school functioning, and peer interactions. Certain chronic illnesses have a greater effect than others on the psychosocial and educational aspects of a child's life, depending on symptom severity and the nature of the treatment. Numerous counseling interventions address the unique needs of these children, particularly regarding school reintegration. This entry provides an overview of common childhood chronic illnesses, discusses psychosocial and educational implications, and describes effective counseling interventions used with this population.

### Common Childhood Chronic Illnesses

#### ***Asthma***

Asthma is currently the most common childhood illness, affecting approximately 5 million children under the age of 18 in the United States. Asthma is a respiratory condition characterized by an obstruction of the airway; it can result in wheezing, coughing, shortness of breath, chest tightness, and fatigue. Attacks may be triggered by allergens, environmental conditions, exercise, or stress. The severity and timing of asthma attacks vary. They can result in limitations on physical activity and increased frequency of medical visits. Treatment varies depending on severity and may consist of self-administered inhalers, nebulizer treatments, or hospitalization. Side effects of these medications can include hyperactivity, anxiety and depression, drowsiness, and impairment in memory and attention.

#### ***Diabetes***

Diabetes mellitus (DM) is an autoimmune disease affecting metabolism. There are two different

types—type 1, which is insulin-dependent or juvenile diabetes, and type 2. Type 1 DM affects approximately 1 in 400 to 600 children and results in permanent insulin deficiency. Treatment for type 1 DM involves regular blood glucose monitoring and daily self-administered insulin injections or the use of an insulin pump.

Type 2 DM is found in 10% to 20% of newly diagnosed cases of juvenile DM. The recent increase in the incidence of childhood obesity is likely responsible for recent increases in type 2 diagnoses. Type 2 DM is characterized by insulin resistance, resulting in chronically high levels of insulin in the body. Treatment of type 2 DM involves strict management of diet and exercise and the administration of oral medication or insulin injections. Based on the nature of the disease and required treatments, diabetes has been found to affect the learning process, mood and attention, and social interactions.

#### ***Juvenile Rheumatoid Arthritis***

Juvenile rheumatoid arthritis (JRA) is an autoimmune condition affecting approximately 200,000 children in the United States under the age of 18. There are three subtypes of JRA: pauciarticular (least severe), polyarticular, and systemic (most severe). Symptoms include stiff and swollen joints, limited mobility, pain, and occasional fevers and rash. Severe JRA can impact bodily organs as well. Treatment for JRA includes medication, limiting activity, and participating in therapeutic exercise programs. Pain and stiffness associated with JRA can affect writing, physical activity, and school attendance.

#### ***Cancer***

Cancer is the uncontrolled spreading of abnormal cells that can affect various parts of the body. The most common childhood cancers are leukemia (blood cancer), lymphomas (cancers of the lymphatic system), and brain tumors. Because cancer treatments are very intense, both the disease and treatment can have severe impacts. Treatments for cancer often include some combination of surgery, chemotherapy, radiation, bone marrow transplants, and immunosuppressants. Symptoms of the disease and treatment may include nausea and vomiting, fatigue, muscle weakness, and significant changes in appearance (e.g., facial swelling, hair loss, temporary weight gain or

loss). Particular attention should be paid to social adjustment, peer relationships, and the emotional well-being of the child.

### ***Low-Incidence Conditions***

Several less common conditions also affect children in their family, social, and educational environments. Low-incidence conditions include cystic fibrosis, epilepsy/seizures, stress-related conditions (headaches, stomach pain), enuresis, encopresis, gastrointestinal disorders, blood disorders (e.g., hemophilia), migraines, heart conditions, and infectious diseases.

## **Psychosocial and Educational Implications**

### ***Family Implications***

Caring for and raising a child with a chronic illness can lead to innumerable burdens on the parent or primary caregiver. Parents must become knowledgeable about the condition, serve as the principal informant to medical professionals, and deal with the financial consequences of the illness. Compared to parents without an ill child, these parents report higher levels of role strain, or stressors associated with the parenting role, as well as frustration and conflict about division of labor and expectations. Parents may also demonstrate increased levels of anxiety and over protectiveness, they may have lowered expectations for their ill child, and they may fail to provide boundaries or consistent discipline for the child.

Caring for a chronically ill child may also result in work-related and marital stress as well as compromised personal self-care. Such stressors can often lead to marital separation and divorce. Gender differences have been noted in how coping relates to marital adjustment. Women demonstrate a negative association between marital adjustment and the tendency to use avoidance strategies to deal with their child's illness, while men indicate that marital satisfaction is associated with positive interpretation and growth. Women, who have a tendency to use avoidance strategies, often experience a strain on their marriages, while for men, interpreting the situation as positively as possible leads to greater marital satisfaction.

Childhood chronic illnesses can also affect siblings. Research suggests that siblings experience increased psychological distress, most frequently

internalizing disorders. Siblings may feel neglected due to increased attention toward the ill child, thereby leading to feelings of distress and isolation. Adaptive functioning of siblings has been linked to family cohesion, social support, and maternal mood or psychological distress. Furthermore, sibling adjustment is influenced by individual factors such as age at diagnosis, gender, birth order, and illness characteristics.

Overall, the most prevalent predictors of well-being in families with a chronically ill child include flexibility, integration into a supportive social network, balancing the demands of the illness and family needs, clear boundaries, effective communication, active coping, and the encouragement of development and growth within the family.

### ***Social Implications***

Several characteristics of diseases and their treatments have been shown to affect children's relationships with peers. Peers are a critical component of the socialization process and heavily influence the behavior of children. Limitations on physical activity resulting from pain, fatigue, or other physical restrictions can limit participation in peer-oriented activities, thus resulting in fewer opportunities to socialize. For instance, a child with asthma may not take part in sports or games that are physically intense. Likewise, changes in physical appearance from the illness can result in negative self-perceptions and negative reactions from peers. A child who has lost his or her hair from chemotherapy may be teased or ostracized by other children. Children with cognitive impairments (e.g., problems with intelligence, memory, or attention) also may be more prone to peer difficulties, which may be attributed to their inability to both understand social information and express social behavior. Likewise, visible differences resulting from illness may lead to increased levels of teasing and bullying.

### ***Educational Implications***

Making school accommodations for a chronically ill child is necessary to prevent social, emotional, and academic problems. Many illnesses result in increased absences from school, thereby causing a child to fall behind in schoolwork. Certain illnesses may result in prolonged periods of school absence or hospitalization. Reintegration into the school system may result in additional concerns such as the fear of falling

behind academically (e.g., having to repeat a grade), worrying about what others may think or say, and concern over having missed important school activities.

Some illnesses require a child to make several daily visits to the school nurse to monitor or administer medication or address symptoms associated with the illness. More nurse visits can lead to feelings of being different, more responsibility for the child, and potentially negative attention from peers.

## **Effective Counseling Interventions**

### ***Family-Based Interventions***

Several pediatric family interventions focus primarily on psychoeducation for parents. More specifically, some of these interventions for children with chronic illness involve working with the family to increase treatment adherence or to address family trauma. Because adherence regimens can create additional conflict within the family system, interventions addressing family conflict are also beneficial.

### ***Social and Behavioral Interventions***

Cognitive-behavioral therapy (CBT) has been found to be effective for helping children cope with the additional stressors of having a chronic illness. CBT addresses maladaptive thinking patterns and behaviors and aims to replace them with healthier coping strategies. Primary goals with this technique include changing thinking and behavior patterns to reflect a more effective approach to managing stress and solving problems.

Stress management involves learning to relax in order to decrease tension and changing the way the child thinks about the illness. Various methods of relaxation include progressive muscle relaxation, passive relaxation, and guided imagery. The aim of relaxation training is to create a physiological state that is incompatible with the anxious physical and emotional reactions. Relaxation, along with distraction, is often used to manage the stress of painful medical procedures such as shots or blood draws.

Because children may be teased by peers as a result of the illness, it is important to help the ill child enhance social skills. Teaching children strategies and behaviors to manage teasing or bullying is critical. Because illnesses can have such a profound impact on the child's social development and relationship with

peers, it is essential to address peer relationships, especially at school.

Another CBT method involves increasing approach coping skills. Approach coping has been shown to be more effective than other methods, such as avoidant coping. While at times avoidance coping might be desirable to the child, CBT interventions designed to help the child learn to actively approach stressors and actively solve problems have been shown by research to be more effective. Approach strategies include the use of problem-solving techniques to gain mastery over coping. For example, a child with diabetes is taught to actively manage dietary intake and insulin treatments in the school environment instead of avoiding these undesirable activities. This method also includes encouraging the child to identify and discuss emotional stressors associated with the illness.

### ***Educational Interventions (Systems Approach)***

Because children spend a majority of their time in school, accommodations within this setting are necessary. Schools address the unique needs of children by developing a 504 plan or an Individualized Education Plan (IEP). A child with a chronic illness qualifies for a 504 plan when the illness interferes with daily functioning in the educational environment but the child has not been formally identified for special education services. An IEP is developed for children diagnosed with a learning disability, communication impairment, or emotional disturbance when the child's needs warrant special education services. Both plans outline specific objectives and modifications to implement in the schools to best meet the educational needs of the child. It is necessary to become familiar with the specific goals and objectives of both IEPs and 504 plans to advocate for the child within the school setting.

### ***Integration/Reintegration***

There are many challenges facing a child returning to school. For example, children may have to cope with changes in physical appearance, daily administration of medication, physical effects of the illness (e.g., fatigue), social isolation following prolonged school absences, and making up missed work. Accommodations can be made to decrease the stress of returning to school. Some examples include shortening the school day initially, helping with note taking,

using a tutor, or using special equipment to assist with learning. Returning to a routine quickly and helping the child maintain normal activities is very important. Facilitating good communication among the school, healthcare professionals, student, and family is critical.

## CHRONIC ILLNESS

---

Chronic illnesses are those incurable conditions that are not contagious, but have multiple risk factors and often involve extended periods of decline resulting in increasing functional impairment. Examples of chronic illnesses include hypertension, asthma, diabetes, and multiple sclerosis. Living with a chronic illness presents many challenges, not only for the person with the illness, but also for family members who must adapt to the changing life circumstances that often accompany ongoing health concerns. Evidence suggests that the quality of life of persons living with chronic conditions is mediated by behavioral and social mechanisms. Beginning with diagnosis, counselors can play a very important role in assisting patients and families with adjustment to chronic illness, assessing quality-of-life issues related to the

illness, and developing interventions to help clients learn new skills and ways of coping with challenging situations. Counselors can also help physicians and the healthcare team to understand the multidimensional psychosocial needs of patients and families.

### Diagnosis

The diagnosis of a chronic illness can result in both immediate and long-term psychological challenges. Diagnostic tests and ongoing treatments can be physically painful and emotionally stressful for both patients and families. Disbelief, denial, anger, and depression are common reactions to a diagnosis of chronic illness. In many cases these are understandable responses to the situation. However, patients and families may need assistance to look beyond these responses in order to adopt new ways of coping and more realistic goals regarding their lives and the future. For example, denial may be helpful in assisting patients and families to get past the initial crisis point of diagnosis. However, denial has sometimes been associated with an individual's resistance to following a medical regimen or medical advice, which can lead to negative health consequences. In general, in order to provide the most effective services, it is important for counselors to have a basic understanding of the nature of the illness, the multiple demands of the procedures involved in diagnosing and treating the illness, the potentially ongoing aspects of medical care, and the prognosis of the illness.

### Chronic Illness in Adults

Once diagnosed, adults are confronted with the process of adjustment to living with a chronic illness. This process is often ongoing, depending on the nature and course of the specific illness. Adjustment is complex, often involving emotional, cognitive, behavioral, physical, and social components. Emotional adjustment can include dealing with feelings of helplessness, being overwhelmed, and fear of the future. Cognitive components may include difficulty with concentration, hypervigilant appraisals of the illness and one's condition, and decline in short-term memory functioning. Behavioral concerns include role fulfillment and role change in an individual's life and meeting the demands of the illness (e.g., doctor visits, taking medications as prescribed). Physical components of illness may include loss of mobility, physical adaptations needed

at home or work, or not being able to drive. Finally, social concerns often focus on personal relationships, social support, the stigma of chronic illness, and social comparisons with others. The combined effects of these adjustments and changes brought on by chronic illness represent an enormous challenge to the patient at a time when most personal resources are very low. Therefore, assistance from a counselor is extremely important in order to support the individual in this process of adjustment.

### **Chronic Illness in Children and Adolescents**

Many children and adolescents experience chronic health conditions. While all children have times of sickness and health in their young lives, children with chronic illnesses have ongoing conditions that affect their normal activities and that may require extensive medical care, including hospitalizations or home health care. Examples of chronic illnesses include asthma (the most common condition), diabetes, cerebral palsy, cancer, epilepsy, spina bifida, AIDS, congenital heart problems, and sickle cell anemia.

Young people with chronic health conditions often face a wide range of problems related to their disease. These can include feeling “different” from other children, frequent doctor and hospital visits, having to endure painful or difficult medical treatments, and hospital stays that can be frightening or lonely. A young person’s reaction to both the diagnosis and the disease will be heavily affected by his or her personality, the specific illness, his or her developmental stage, and perceived support from family and medical personnel. Counselors can help children and their families cope with illness using behavioral techniques such as relaxation, biofeedback, and positive practice and by modeling healthy behaviors for children. Counselors can also help children cope with their illnesses by providing them with a forum in which they can speak openly about their disease and their experiences. Due to the chronic nature of these childhood diseases, depression is often a side effect in children, who may feel that they will never be “normal,” or like other children. Counselors should be aware of the signs of depression in children and should assess for these regularly. Play therapy and expressive therapies, such as art, music, and drama therapy, can be helpful in allowing children to

explore their emotions and process experiences related to their condition.

### **Family Issues**

Patients do not experience chronic illnesses alone. Families and significant others typically go through a number of life-altering new challenges and stressors related to the illness over time. For example, the presence of chronic illness often results in increasing financial, time, and emotional burdens on patients and their families. Many individuals who experience chronic illness have a loss of income due to a decrease in days at work or the loss of a job, and at the same time they have an increase in expenses related to medical bills, therapies, and medications. The primary caregiver (typically the spouse, parent, or adult child) of the ill person may need to decide whether to give up working in order to care for the patient. Balancing the new role of caregiver with possible concurrent roles of parent, breadwinner, head of household, etc., is a daunting challenge for many individuals.

Family relationships and perceived social support can be important contributors to the effective management of chronic illness, reducing some of the stressful impacts of the disease. Significant positive relationships may also affect the ability of the patient to develop and implement coping skills, follow medical instructions, recover from surgery or other procedures, and perform in-home tasks and adapted vocational roles. Some patients with chronic illnesses report closer relationships with family and friends as a result of their diagnosis and illness. Patients who perceive more social support are typically better able to cope with the effects of their illnesses than patients who report less perceived support.

On the other hand, the effect that chronic illness can have on interpersonal relationships can be very difficult for some patients and families. For example, families often struggle to understand what the patient is experiencing and whether he or she is doing too much or too little to cope with the situation. Unrealistic expectations related to how the patient “should” cope with the illness can cause a number of difficulties. Families often report a sense of helplessness and fatigue, especially when trying to adapt to new roles necessitated by changes related to the chronic condition. In an effort to provide support, families may offer advice that is not always helpful or welcomed by the

patient. These interactions related to changes accompanying the chronic illness often result in stress and frustration, which may lead to increased depression and anxiety. The counselor can help patients and families learn to listen and communicate more effectively with one another. These skills, in turn, may strengthen bonds of social support, which contribute to better adjustment and quality of life.

### **Diversity Considerations**

Awareness of special characteristics of patients' backgrounds and environments is important in understanding individual and family responses to illness and treatment. Counselors may want to explore the cultural heritage and religious values of clients in order to respect and incorporate some of these key strengths and resources in their work with patients. For example, we all have health schemas related to the cause or reason for illness (e.g., we may believe the cause is natural or supernatural or that the illness is a punishment for wrongdoing). Exploration of these beliefs can provide valuable information about patients' views of themselves, the world, and potential healthcare interventions. Some cultures are more interdependent than others and value a different style of decision making than other cultures that value independence. Different groups may view medical treatments or death in very different ways, and understanding these differences can be extremely helpful in dealing with patients and families who are facing life crises or decisions with long-term consequences (e.g., having a feeding tube inserted that extends the patient's life but does not lead to better quality of life over time). Some cultures clearly value extensive familial-social support networks, which can be a great asset to individuals or families facing chronic illness. Other cultural groups, because of language and background, may lack competence in verbal expression or use cultural idioms of distress unfamiliar to the counselor. In many cultures, there is a stigma related to seeking help outside the family. As in other areas of counseling, it is critical to examine one's cultural competence when working with clients and to be aware of one's own limitations of background and experience. Consultation with colleagues is often helpful.

### **Assessment**

Performing assessments can be useful when working with individuals who are chronically ill and their

families. For example, assessments can be used to gain information related to patients' cognitive ability to adhere to medication and treatment requirements, their competency to make medical decisions, and their overall psychological capacity to handle new challenges. Assessments can also be performed to help with treatment planning.

There are a variety of ways to perform assessments, including clinical interviews, formal paper-and-pencil measures, and basic neuropsychological screening. Relevant areas to address in the clinical interview include personal and environmental strengths, perceived barriers to adjustment, and personal meaning-making regarding the illness. Family members, especially the primary caregiver, should also be interviewed and included in the assessment. Interviews may be conducted separately for caregivers depending on the type of information that is needed. Formal assessment instruments may cover areas such as depression, anxiety, quality of life, and caregiver burden. Neuropsychological screening can be suggested if there is a question of diminished cognitive ability. One caution relative to assessment is that a variety of symptoms overlap the domains of physical illness and emotional distress. For example, aspects of some illnesses include change in appetite or sleep patterns, loss of energy, or difficulty in concentration, which are also symptoms of depression. It is important to remember that the purpose of all assessment is to inform the counselor about how best to support and promote the adjustment and care of patients and families.

### ***Interviews: Personal Meaning of Illness***

Research has shown that patients' ascribed meanings can be used to screen for maladaptive coping and to predict health outcomes and quality of life. For example, developing a chronic illness may cause a shift in personal life goals or worldview. After an illness diagnosis, patients' perceived meanings of their own lives can be drastically altered. For example, many individuals pay more attention to issues of spirituality and faith than they did prior to diagnosis. Patients may also become more introspective and reflective.

With chronic illness, major transformations sometimes occur in patients' lives as they struggle to make sense of the diagnosis. Meaning-making is an ongoing process of evaluation, exploration, and weighing of values that takes place when people are faced with life circumstances that in many ways are beyond their

control. The search for meaning is not only an intensely personal response to chronic illness, but it can also be viewed as an interactional process involving family or significant others. Existential questions such as “Who am I now in relation to my family or to this person I love so much?” or “What will my identity be now that I can no longer work and provide for my family?” may arise. It is important for the counselor to attempt to understand the meaning of illness for both the patient and the family, because the very process of trying to understand itself helps to foster cooperation, coping, adjustment, adherence, and empowerment.

### ***Interviews: Family Members and Caregivers***

Because of the challenges that family members experience as a result of chronic illness, it is important to consider the strengths and resources available to family members and more specifically to the primary caregiver. Learning about the needs and potential range of difficulties associated with the illness from each person’s perspective also helps the counselor assist family members in finding positive ways to cope with the situation.

### ***Formal Measures: Emotional Changes***

It is often helpful to have a baseline measure of the patient’s emotional functioning. There are a number of standard paper-and-pencil measures that can provide information about a variety of mood states, including depression, anxiety, stress, intrusiveness of illness, hope, and loneliness. This information can assist the counselor in setting priorities for treatment planning. It is important to remember that changes in mood may be a normal reactive response to the diagnosis and circumstances of illness. However, mood change can also be a manifestation of some aspect of the disease itself. It is also possible that some of these symptoms may have been present before the diagnosis of chronic illness and can represent comorbid conditions. The counselor will want to consider these alternative explanations and to explore the source of the mood disturbance with the patient and the family or significant others. Depending on the severity of the condition, this discussion may be followed by a suggestion that the patient or family consider seeking consultation with the primary care physician regarding these concerns.

### ***Formal Measures: Quality of Life***

Quality of life (QOL) is often defined as an overall state of physical, emotional, and social well-being. The literature in this area often includes other facets of quality of life such as role functioning. Physical functioning may be assessed by using a checklist of activities of daily living (ADLs) or by determining the patient’s ability to perform everyday tasks. Emotional functioning includes assessment of variables such as those described in the previous section. Social functioning is often assessed by measuring actual or perceived social support. Role functioning is assessed in terms of the patient’s ability to perform functions related to work, parenting, or maintaining a career.

Assessment tools have been developed that attempt to assess the physical, psychological, and social changes that occur as a result of chronic illness. These instruments have also been created in order to determine if specific interventions or treatments improve not only physical symptoms as assessed by medical staff but QOL as reported by the patient. Quality of life is based on the patient’s perception of how the illness affects his or her day-to-day life. Thus, these tools are typically self-report instruments that provide the counselor with an understanding of how the patient views his or her life and functioning in various areas.

There are two primary approaches to measuring quality of life. First, global questionnaires provide a broad, overall view of the patient’s functioning. Such questionnaires often generate useful health profiles. The second approach consists of instruments that are more disease-specific and that focus on problems associated with single disease states, patient groups, or areas of function. These approaches are not mutually exclusive and each has specific advantages.

## **Counseling Interventions**

In order to help individuals with chronic conditions deal effectively with adjustment to illness, counselors often employ a variety of interventions that have been shown to be useful in decreasing anxiety, fostering social support, and reducing symptom severity. Behavioral and cognitive-behavioral techniques are the primary interventions used in health psychology and medical settings. These approaches are often focused on symptoms, identify factors related to a particular problem, and attempt to modify the factors that cause or maintain the problem. These strategies have

been found to be effective in enhancing an individual's compliance with medication and other health routines, helping with symptom control (e.g., pain management), and increasing a sense of self-efficacy, or an individual's sense of control over his or her own life and disease. Some of the specific techniques used in these approaches include relaxation training, biofeedback, differential attention, goal setting, and positive practice. Because stress, anxiety, and pain are often associated with illness and medical interventions such as surgery or chemotherapy, the use of relaxation techniques that include deep breathing and decrease arousal are often helpful to the patient. Cue-controlled and differential relaxation are useful in the generalization of the relaxation response to settings outside of treatment. These techniques are often combined with other interventions, such as distraction, comforting self-talk, imagery, and systematic desensitization to provide the patient with a repertoire of helpful skills.

### ***Stress Management***

Stress management is an intervention of particular importance, as it can help patients deal with chronic, ongoing conditions as well as crisis situations. Knowing how to manage stress can also help prevent the onset of headaches, muscle tension, and the development of other chronic diseases such as diabetes, pulmonary dysfunction, and rheumatoid arthritis. Many stress management programs are disease-specific and present a series of patient education modules offered over a period of weeks in a group format. Typical modules include an explanation of how stress affects the body, challenges patients face, problem solving related to those challenges, presentation and practice of relaxation techniques, and possible treatment options. Homework assignments, involvement of family members, and discussion of misconceptions about the illness are often incorporated.

### ***Self-Efficacy Enhancement***

Two standardized courses have been developed to help patients manage the symptoms and complications of their conditions. The Arthritis Self-Help Course and the Chronic Disease Self-Management Course (both conceived by Kate Lorig at Stanford University) are 7-week courses that are offered to groups of eight to ten patients. A variety of topics are addressed, including goal setting, problem solving,

and exercise. Participants are paired with one another and asked to check in with their partners on at least a weekly basis. Reports of the extremely positive and long-lasting outcomes of these courses have noted that the greatest predictor of improvement is increased self-efficacy. Altruism, or the opportunity to help others in the group with ideas, suggestions, or support, has also been noted as important to participants. Training is available for counselors to become certified to offer these courses.

### ***Support Groups***

Support groups can help patients deal with aspects of the disease, the trauma it has caused, and its future implications in a way that promotes a sense of personal coherence, coping, and adaptation. Support groups may also help chronic illness patients engage in a reappraisal of their experience, focus on meaning-making, and integrate their experience into their personal narrative. By joining a support group, individuals often establish new connections with others who may be having similar experiences. Group participants typically give and receive social support, which appears to buffer stress and to benefit persons with chronic illness.

Support groups for family members and caregivers can also be very beneficial. Such groups allow individuals a safe place to express the concerns and frustrations inherent in their position. Others who care for persons with chronic illnesses can commiserate with the difficulties that are faced and offer suggestions about how to approach specific problems. Laughter over some of the humorous circumstances that occur that “outsiders” wouldn't understand can be very therapeutic.

### ***Additional Roles of the Counselor***

In addition to assisting the patient and family through emotional aspects of adjustment to chronic illness, the counselor may be called upon to help clients advocate for themselves with physicians, the medical system, insurance companies, or others involved in the patient's care and treatment. It is helpful to know enough about the healthcare system to support clients as they seek answers to the myriad questions that arise as they face new dilemmas and work toward managing challenging life circumstances. The counselor may also work as a liaison between medical personnel and the patient and family, supporting and interpreting the communication so that everyone clearly understands

explanations, instructions, and the implications of treatment choices and decisions.

## Future Directions

In the future, there will be increased need for counselors who specialize in areas such as genetic counseling. With the completion of the Human Genome Project, there is expanding development of genetic testing for a variety of inherited diseases and conditions. Undoubtedly, with more advances in research, there will be broader uses of genetic testing for growing segments of the population.

The future will most likely bring the expansion of health promotion programs. In order to contain health-care costs, prevention programs targeting health behaviors such as weight loss, exercise, and smoking cessation will become more widespread. Counselors with special expertise in psychoeducational presentations and group work will be needed to deliver these interventions.

Finally, increasing access to computers and familiarity with technology will provide patients and families with new avenues of information and support. Counselors will want to be aware of resources that are available online to clients in rural areas or those who are not able to physically access other opportunities or interventions.

## CHRONIC PAIN

---

The classical model of pain, first articulated by the philosopher Descartes in the 17th century, regarded pain as a sensory experience triggered by tissue damage. Despite the fact that this model is unsupported by empirical research, it continues to be a common misconception. Research on pain has demonstrated that it is a complex biopsychosocial phenomenon, with sensory, affective, cognitive, and social components. The International Association for the Study of Pain defines pain as being both a sensory and emotional experience. It goes on to state that pain is always a subjective experience, and its presence cannot be verified by any kind of objective test. Consequently, the only way of knowing if an individual has pain is through the verbal report or other communication of that individual. Chronic

pain can sometimes persist in the absence of any identifiable physical cause.

In the acute phase following the onset of disease or injury, pain is often more closely associated with nociception. Nociception is a sensory system that alerts the brain to actual or potential tissue damage and initiates self-protective behaviors. Nociception, however, cannot be equated with pain, as nociception can occur without pain, and pain can occur without nociception. In contrast, as pain becomes chronic, its cognitive, affective, and social components tend to play a progressively larger role. Research studies using functional magnetic resonance imaging (f-MRI) have shown that the brain activity observed while experiencing physical pain is similar to brain activity observed while experiencing social pain or “hurt feelings.” This blurs the distinction between physical and social pain. Similar f-MRI studies have also found that physical pain and imagined pain also produce similar brain activity.

The complex nature of pain has led some to classify pain as being either “real” or “not real,” but this is a false dichotomy. Consider the example of someone whose foot is traumatically amputated in an accident. Many who experience this type of injury will experience “phantom pain,” or pain in the missing foot. Where is this pain? Is this pain “real” and “in the foot”? Or is this pain “not real” and “in the head”? Pain is an inherently subjective experience, and subjectively, this pain is clearly in the foot. Objectively though, there is no foot there to hurt. Consequently, it could be argued that the pain is actually in the stump, where the severed, damaged nerve ending is transmitting the wrong signal to the brain. However, the patient could counter that the pain cannot be in the stump, because the stump itself does not hurt. It could also be argued that the pain is in the brain, because the brain is involved in all subjective experience. The fact that all three of these explanations are correct in their own way illustrates the complex nature of pain. Because all pain is a subjective experience, the individual’s report of pain should be accepted. At the same time, knowing that chronic pain is a complex and multidimensional phenomenon, the various factors influencing pain need to be explored.

### Pain and Development

Developmentally, pain is one of the first experiences communicated, when the infant cries in response to

painful sensations and draws the attention of caregivers. Thus, from the earliest times of life, pain is experienced in association with emotional distress and is expressed within a social context. It is through these experiences that the child comes to understand the meaning of the word *pain*, associates sensory and emotional experiences with it, and begins to develop expectancies about what other people will do if pain is experienced.

Within the first few years of life, pain develops into a complex experience. For example, a child who is knocked down by a playful dog and sustains a bruise may cry and complain of pain. Upon closer inspection, however, this child’s report of pain may include unpleasant physical sensations and also a cognitive appraisal of danger, fear of harm, and anger at the dog as well as a desire for the comfort and protection of the parent. If this child’s complaints of pain can be alleviated by a hug and cookie, though, it affirms that this particular experience of pain was not purely sensory information related to tissue damage but was rather an undifferentiated amalgam of unpleasant physical sensations, cognitions, and emotions that was accompanied by a desire for the support of others. In this manner, the perception of pain and its meaning evolves over the course of life.

Most commonly, emotional distress acts to magnify the level of pain caused by organic pain generators. However, a construct that has been used to explain some types of chronic pain is alexithymia (meaning “without words for feelings”). Alexithymia may occur when a person is raised in an emotionally impoverished environment and as a result is unable to express or even recognize emotional states. Such a person, being unable to recognize emotional pain, may be unable to differentiate it from physical pain and may report experiences of both types simply as “pain.” Because medical treatment for physical pain generally does not reduce emotional pain, this can complicate treatment, as it may not be clear what kind of pain is being reported.

### Theories of Pain

Modern theories of pain were influenced greatly by Melzack’s gate control theory, which postulated that emotional arousal could alter pain perception by opening and closing perceptual “gates.” Nociceptive information pertaining to pain travels through spinal pathways that take it through areas of the brain known to be associated with affect; limbic structures, the

medial thalamic nuclei, and the anterior cingulate play especially important roles. This has led to the use of the phrase *limbically augmented pain syndrome* to refer to states where chronic pain seems to be closely intertwined with vegetative depressive signs.

One recent theory proposed by Melzack, neuromatrix theory, attempts to explain a variety of pain-related phenomena. The neuromatrix is conceptualized as being a widely distributed neural network in the brain that is in part genetically determined but is also affected by sensory experiences, emotional arousal, chronic stress, and other factors. According to this theory, the neuromatrix interprets nociceptive information and in so doing produces the experience of pain.

Research on stress and the endocrine system by Heim, Bremner, and others helps to shed light on the relationship between chronic pain and chronic stress proposed by neuromatrix theory. For example, patients who report a history of emotionally traumatic events have been found to exhibit increased pituitary-adrenal and autonomic responses to stress compared with controls. This increased reactivity under stress may explain the increased vulnerability to chronic pain that has been observed in those who have suffered emotional traumas.

### Pain in the Medical Setting

Research suggests that pain may be the most common single symptom seen by primary care physicians. The National Center for Health Statistics has estimated that up to 80% of office visits to primary care providers involve some complaint of pain, and this accounts for over 35 million new office visits a year. One large study on medical expenditures in managed care found that the medical treatment costs associated with chronic pain exceeded the costs attributable to the treatment of other disorders, such as heart disease, respiratory disease, or cancer. However, unlike these other diseases, which can be diagnosed by objective medical findings, pain is a subjective experience. As a result, the goal of medical treatment for pain is usually to change the verbal report of pain.

Chronic pain can affect any part of the body. However, certain types are more common. In particular, low back pain and headaches are commonly reported. For some types of chronic pain, there is an obvious organic pain generator. However, chronic pain sometimes exceeds what can be explained by objective medical findings and can

occur in patterns that cannot be explained on a purely anatomical basis.

### The Assessment of Pain

In addition to heart rate, respiration rate, blood pressure, and body temperature, the presence or absence of pain is regarded as one of the five vital signs in medicine. While the other vital signs can be objectively assessed, though, pain cannot. Typically, patients are asked to rate their pain in one of two ways, the first of which involves using a visual analog scale or VAS. On the VAS, pain is assessed by having the patient make a mark on a 10-centimeter long line, where one endpoint is labeled “no pain” and the other endpoint is labeled with some description of extreme pain. Alternately, patients are asked to rate their pain from 0 to 10 using a numerical rating scale or NRS.

The assessment of pain using either the VAS or the NRS is complicated by the fact that these tools are hampered by lack of standardization, which greatly impairs their value. First of all, extreme pain is defined in a variety of ways on these tools. For example, on these measures extreme pain is alternately defined as “the worst pain you can imagine,” “pain so bad you want to die,” or in any number of other ways. However, each of these definitions influences the rating, and a person with moderate pain who was also suicidal might rate pain differently using the two definitions above. Secondly, there are no standardized instructions. For example, these tests have no instruction regarding bodily location of pain, nor do they address the issue of multiple pain sites. Thus, if a patient has a headache of 5 on a 10-point scale and a back ache of 3, it is not clear what number will be reported if the patient is asked simply to “rate your pain level.” When patients have two or more pain complaints, they may alternately pick the highest number, try to average them, or sometimes add them together. Because of this lack of standardization, the numerous variations of the NRS and VAS are not equivalent, and this may influence the results in a variety of ways. As a result, while the other vital signs all have agreed-upon means of assessment and cutoffs for what is high, pain has neither.

More recently, new assessment tools have been developed that have attempted to address this problem. In particular, the Battery for Health Improvement 2 (BHI 2) is the first test to offer a multidimensional assessment of chronic pain with standardized instructions and established validity and reliability. The BHI

2 assesses pain in multiple locations, overall pain, pain variability over time, pain tolerability, and pain-related cognitions. These pain reports can be compared to national norms for both community members and medical patients and also to patients in the same diagnostic category. Further, this instrument also includes a variety of other scales that assess the biopsychosocial context in which the pain occurs.

## Pain Management

Because chronic pain is a biopsychosocial phenomenon, treatment for pain optimally involves a multidisciplinary team that addresses pain's biological, psychological, and social components. The biological aspects of chronic pain are addressed by physicians whose task is to evaluate the patient and identify any injury or disease that may be contributing to the pain experience. Treatment may involve a variety of medications, including medications for pain or inflammation as well as medications specific to any disease that may be present. Antidepressant medication may be prescribed to help with associated affective distress. Additionally, though, as pain and affect are closely related, some antidepressant medications also have an analgesic effect. Medications may be prescribed for insomnia, which is frequently seen in patients with chronic pain. Medical treatment can also involve surgery, injections, and other invasive procedures. Lastly, the physician may refer the patient for physical therapy as well.

The psychosocial aspects of chronic pain are usually treated by mental health professionals who can help patients with chronic pain in several different ways. First of all, psychological treatment has commonly been used to help patients manage their pain. However, more recent research has shown that psychological treatment can significantly reduce pain as well. Counseling the individual with chronic pain may involve helping this person to develop better techniques for pain management. Individuals with chronic pain sometimes "catastrophize" and view their situation as being worse than objectively is the case. Individuals with chronic pain can also become somatically preoccupied. This preoccupation with pain may heighten the pain experience and increase the level of affective distress and suffering. Catastrophizing and somatic preoccupation can lead an individual with chronic pain to feel extremely fragile, and this can lead to excessive self-limiting behaviors out of an

irrational fear of self-harm. This self-limiting behavior can in turn lead to a progressive physical deconditioning and to further disability. Helpful techniques involve teaching the patient to shift attention away from the pain, to develop a more realistic appraisal of the pain and any associated disability, and to identify desirable activities that the individual should continue to engage in.

The onset of chronic pain may require the patient to make a multitude of lifestyle changes. Patients with chronic pain can often benefit from the opportunity to discuss all of these new life challenges with a mental health professional and from using a problem-solving approach to address whatever changes are necessary in work, home responsibilities, hobbies, and other activities.

Because chronic pain and any associated disability can be stressful, offering the patient stress management techniques is often helpful. This may include relaxation training or biofeedback. Stress management is important, because stress tends to increase physiological arousal levels. As noted above in gate control theory, physiological arousal tends to increase the experienced intensity of pain. This can lead to an ever-worsening syndrome, where pain leads to stress, and the stress heightens the pain experience, which then in turn worsens the stress. It should also be noted that some types of chronic pain, such as chronic tension headaches, can be produced entirely by stress.

Chronic pain is also commonly associated with depression, anxiety, and anger. Individuals with chronic pain may feel despondent or angry about having to constantly cope with pain and may be fearful about the future. As with stress, strong emotions also tend to increase the level of experienced pain. The term *suffering* is sometimes used to refer to the combination of pain and emotional distress that is felt. Helping the individual with chronic pain to reduce the level of emotional distress will reduce the level of suffering and may reduce the level of pain as well.

Chronic pain is often associated with insomnia, as the patient cannot get comfortable and also may be too distressed to sleep. In addition to stress management training, there are specific techniques for insomnia control that are sometimes referred to as sleep hygiene training. Research has shown that these techniques are about as effective as medication for treating insomnia. Additionally, unlike medications, these techniques have no side effects.

When an individual suffers from chronic pain, it may have an impact on the entire family. The individual with chronic pain may no longer be able to take care of his or her usual household responsibilities, and this may be very disruptive. While a healthy family will tend to rally behind the individual with chronic pain, the dysfunctional, unsupportive family may refuse to adjust to the chronic pain condition. This may increase the emotional distress of the individual with chronic pain and force the individual to perform activities that worsen the pain. On the other hand, overly supportive families may encourage the individual with pain to adopt a passive role, which in turn may only increase disability. The quality of life of the individual with chronic pain can improve considerably if the family can learn to provide the optimal level of support.

## CIGARETTE SMOKING

---

Cigarette smoking is a behavioral risk factor for disease and one that is amenable to intervention by counseling psychologists. Clients who seek help for emotional and

behavioral problems are more likely than others to be cigarette smokers, and counseling psychologists should become familiar with treatment guidelines that exist. All smokers should be encouraged to quit, and brief interventions are effective for motivating smokers to consider quitting. More intensive treatment has been shown to be effective, but such intervention may require specialized training. Smoking is a chronic condition, and relapse is common. This entry provides statistics and information about smoking as well as guidelines for counseling the smoker.

### Statistics

Cigarette smoking increases risk for disease, and cessation can reverse this risk. It is estimated that male smokers lose an average of 13.2 years of life and female smokers lose 14.5 years due to smoking. However, cessation can minimize these health risks. Individuals who stop smoking before age 35 avoid 90% of the risks associated with cigarette smoking.

The percentage of people who smoke cigarettes in the United States has declined from highs in the mid-1970s of 42% to approximately 28% today. Trends suggest that there is a deceleration in this decline. There are also some indications that there may be a slight increase in tobacco use among teens and college students. Data from the Monitoring the Future Study conducted at the University of Michigan suggest that in 2005, 1 in 11 eighth graders and 1 in 4 twelfth graders had smoked in the past 30 days. While these rates are lower than in the past, they remain at an unacceptably high level.

### Hazards

The harmful effects of cigarette smoking are well documented, and today there is a growing understanding of the harmful effects of involuntary exposure to tobacco smoke in the environment. In June of 2006, the surgeon general issued a report documenting the harmful health effects of exposure to tobacco smoke and urged greater attention to this problem. Data from this report indicate that approximately 60% of non-smokers in the United States show biological markers indicative of environmental exposure to tobacco smoke. It is likely that there will be even greater attention given to this aspect of cigarette smoking in the coming years, and there will be policy changes such as the implementation of smoke-free workplaces.

Similar policies are currently being implemented in many healthcare facilities.

### Etiology of Tobacco Dependence

Cigarette smoking typically results in nicotine dependence and nicotine withdrawal, two Axis I disorders classified by the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition*. Compared to other drugs of abuse, such as marijuana, cocaine, or alcohol, tobacco is more likely to cause dependence. Recent studies have documented that more than 80% of individuals who report regular smoking meet criteria for nicotine dependence. Likewise, 32% of all individuals who have ever tried any tobacco products progress to nicotine dependence. Comparable statistics for heroin, cocaine, and alcohol are 23%, 17%, and 15%, respectively. Tobacco has a high risk for dependency.

Cigarette smoking is commonplace among psychiatric patients. There are differing perspectives as to why psychiatric patients smoke. Some have suggested that smoking is an attempt to self-medicate emotional symptoms. Research indicates that stress exacerbates urges or cravings to smoke and is associated with relapse. In addition to an association with emotional problems, cigarette smoking is clearly associated with other substance use problems, including use of alcohol, caffeine, and illegal drugs. The more severe the emotional disorder, the more likely that smoking will be present and the greater likelihood of dependence. Additionally, cessation is likely to be more difficult with severe emotional disorders.

### Smoking Cessation

Clinical practice guidelines for working with smokers were developed by the United States Public Health Service in 1996 and revised in 2000. The goal of these guidelines is to provide health care providers with evidence-based recommendations regarding methods for increasing the likelihood of successful smoking cessation. Counseling psychologists, as healthcare professionals, should consider adopting these guidelines with all clients regardless of presenting problems. The guidelines allow for client autonomy while maximizing effectiveness for clients who desire help.

### Assessment of Tobacco Use

For clients who do not want to quit smoking, it is suggested that a brief intervention be provided to help

increase motivation to quit. Clients who want to quit should be provided with assistance using effective strategies. Details can be found in the monograph *Treating Tobacco Use and Dependence* (Fiore et al., 2000), which can be downloaded from the Web.

Healthcare providers should assess the smoking status of every client at every visit. For individuals who smoke, it is recommended that one assess the client's interest in stopping. Depending on the answer to questions regarding desire to quit, a brief motivational intervention is recommended that can enhance motivation to quit for individuals who are not ready to quit and can be the first step in cessation for individuals ready for cessation.

### Role for Counseling Psychology in Smoking Cessation

While the clinical practice guidelines have been in place since the mid 1990s, most studies suggest that healthcare providers do not use the guidelines. For example, physicians frequently fail to counsel clients to quit smoking, although there is some evidence that rates of physician assistance are increasing, and one study showed that over 50% of physicians advised smokers to quit. Most other healthcare professionals (pharmacists, public health nurses, chiropractors, and dentists) use these guidelines less often than physicians. A recent survey of licensed psychologists indicated that psychologists often provide assistance and intervention for clients who want to quit smoking, but like other healthcare providers, they rarely inquire about a client's tobacco use.

Given that psychologists are often in a position to provide effective intensive clinical interventions for smoking cessation or at least to provide brief interventions, it is disappointing that as a health care profession, psychologists are not leading the way. This is particularly important given the high comorbidity seen for cigarette smoking and other mental health problems. As noted earlier, smoking rates are substantially higher for individuals with psychiatric mood, anxiety, and psychotic problems, and these individuals have more difficulty with cessation than individuals without comorbid psychological problems.

Recently, Miles McFall and his colleagues at the Seattle Veterans Administration Medical Center have initiated smoking cessation treatment for patients seeking treatment for posttraumatic stress disorder (PTSD). His data suggest that clients who

received integrative treatment (e.g., treatment for both PTSD and cigarette smoking) were 5 times more likely to abstain from smoking than those who received standard PTSD treatment. More importantly, stopping smoking was not associated with increased PTSD or depressive symptoms. These data are promising, and psychologists should not be concerned that treating nicotine dependence will be contraindicated in the treatment of clients with other emotional problems.

### Brief Clinical Interventions

All counseling psychologists should have the basic clinical skills necessary to implement brief interventions. Long-term abstinence can be greatly increased through the use of brief clinical interventions; the base rate for long-term abstinence is 7% when there is no intervention and 15% to 30% for individuals who receive brief interventions.

Effective brief interventions utilize skills and techniques often associated with motivational intervention strategies. The clinical practice guidelines recommend an approach commonly known as the “Five A’s”: *ask*, *advise*, *assess readiness*, *assist*, and *arrange*. Every client should be asked about tobacco use at every visit (*ask*), and every tobacco user should be encouraged to quit (*advise*). The client’s willingness to quit should be assessed (*assess readiness*), and appropriate assistance should be provided to the client (*assist*). For individuals who are not ready to quit, assistance could be in the form of a brief motivational intervention designed to enhance motivation to change. For those ready to quit, assistance could include providing self-help materials or a referral for a more intensive intervention. Finally, the clinician should arrange to follow up with clients who use tobacco (*arrange*). Follow-up could be as simple as a phone call to assess smoking status or a scheduled visit to discuss cessation plans. During follow-up, the clinician might congratulate success or help address problems as well as anticipate future challenges. For clients referred for intensive interventions, assessment of treatment is important.

### Intensive Clinical Interventions

While all counseling psychologists should be in a position to offer brief clinical interventions for smoking cessation, more intensive intervention will be needed for some clients. These interventions are often

provided by clinicians who specialize in treating tobacco dependence and who work in a setting where the primary focus is on smoking cessation. There is substantial evidence that intensive interventions are more effective than brief interventions with respect to cessation success rates; however, many studies have found that only a minority of smokers participate in intensive interventions.

Evidence for intensive interventions suggests several necessary components. First, assessment should ensure that smokers are willing to make an attempt to quit. A willingness to attempt cessation is critical for success. Second, use of multiple types of clinicians is effective and may be desirable. One clinician might provide counseling strategies related to health risk; another clinician might provide pharmacotherapy; and a third clinician might provide additional psychosocial or behavioral interventions.

Third, since there is evidence of a dose-response relationship, it is recommended that intensive treatment use sessions that are at least 10 minutes in duration and that treatment involve four or more sessions. Fourth, the type of intervention (group vs. individual) does not appear to be important. In fact, telephone counseling has been shown to be effective. Fifth, techniques used should be practical (problem solving or skill training), and social support should be provided within sessions and fostered in the client’s environment.

Finally, pharmacotherapy should be encouraged for all smokers, unless there are particular contraindications for the client. First-line pharmacotherapies include bupropion SR, nicotine gum, a nicotine inhaler, nicotine nasal spray, and the nicotine patch. Many of these are over-the-counter medications and do not need a prescription. Special considerations are needed for teens and pregnant individuals.

As noted earlier, intensive treatment should be used by clinicians with specialized training in working with nicotine dependence. However, all psychologists should be aware of the effectiveness of intensive interventions and should make appropriate referrals for their clients who smoke.

### Relapse Prevention

The vast majority of cessation attempts result in some type of relapse. It is useful to consider the difference between a brief lapse (an isolated event that is followed by continued abstinence) and a more extensive relapse (a period of several days or more of continued

smoking after a period of abstinence). While any form of lapse is very risky and increases the likelihood that the abstinent smoker may return to previous smoking rates, the frequency with which lapses occur suggests that some form of relapse prevention is critical to maximize the chance that a lapse can be followed by continued abstinence, instead of becoming a relapse.

Methods for reducing relapse have included booster sessions, formal relapse prevention training, and enhancing social support. The use of booster sessions alone has not been found to be very useful. Likewise, relapse prevention efforts are at best equivocal. There is some evidence that quickly recruiting individuals who have relapsed into a second course of treatment does not work. Clients who relapse and then try a new pharmacotherapy may fare better in the new attempt.

## COMMUNITY-BASED ACTION RESEARCH

Community-based action research (C-BAR) is a relatively new addition to counseling and counseling psychology research. The research and interventions, or actions, occur at the community level, rather than with individuals, families, or small groups. *Community* is defined as a group linked by common interests, such as young women in a teen pregnancy program, migrant workers, or people living with AIDS.

C-BAR is distinguished from much other research in counseling in that the research is developed and conducted as a collaborative partnership between the counselor-researcher and community members. Sharing project responsibility in this way empowers the community to define its own problems and develop its own solutions. In this collaborative process, the researcher is deeply involved as a coexpert, bringing organizational and research skills to the project. Community members are the other coexperts, contributing their unique experiences, truths, and analyses of why the problem exists and how it may be solved. C-BAR projects are not value-free endeavors; they are often explicitly conceptualized as efforts to promote social justice and equality by empowering those with muted or silenced voices to speak and act on their own behalf.

### C-BAR, the Family Tree

#### *Philosophical Roots*

The emergence of C-BAR in counseling parallels the increasing influence of constructivist, feminist, multicultural, social justice, and qualitative research perspectives. Community-based action researchers believe that truth is relative. They believe that perceptions of reality are shaped by social, political, and economic factors that impact individuals and communities and that these factors determine who gets the power and authority to speak, label, and define reality.

C-BAR is part of a family of action and participatory research, including participatory action research, community participatory action research, critical action research, feminist participatory research, classroom action research, and industrial action research. Adherents of action research debate among themselves about terminology, principles, ideology, goals, and change theories. Some of the disagreements

can be traced to historical as well as philosophical differences.

### **Historical Roots**

There are a number of founders or contributors to the action and participatory research family. The majority of action researchers today stem from the following traditions: (a) social psychologist Kurt Lewin, who coined the term *action research* in the 1940s; (b) the Tavistock Institute of Human Relations in the United Kingdom, which was primarily involved in organization development; and (c) the social movements of the 1970s in the developing world, championed by individuals such as exiled Brazilian philosopher Paulo Freire, author of the banned *Pedagogy of the Oppressed* (1970).

Action researchers today have been classified in a number of ways, including along a continuum with Lewin and his followers at one end and Freire and his adherents on the other. Following the Lewin tradition, researchers engage primarily in problem-solving action research, such as in industrial psychology, and do not necessarily include the community as extensive collaborators in the research process. They also seldom conduct research with commitment to broader social change. At the other extreme of the continuum, in the Freire tradition, is research more typical of the movements of the 1970s and popular education, rooted in social justice and consciously linked to broader social change. These researchers see the community as the vanguard of social change and social justice, and they see themselves, the researchers, as catalysts and supporters of the change process.

### **Commonalities**

In spite of their differences in ideology and goals, most C-BAR researchers share certain values and principles. C-BAR involves collaboration between researchers and the community. C-BAR is a participatory, colearning process and is usually an empowering process for the community. C-BAR attempts to achieve a balance among theory, research, and action. A key commonality is an intent to change something that the participants view as worthy of change.

### **Methodological Approach**

Methods in C-BAR and other types of participatory action research have an extensive history in various

social science and social practice fields. C-BAR methods evolved from such disciplines as anthropology, sociology, psychology, education, public health, nursing, and social work. Today, C-BAR principles are often greatly influenced by feminist and multicultural ideologies. Putting these theories into practice implies that central to C-BAR methods today are issues of gender, race, class, and culture.

In practice, C-BAR uses a method of systematic inquiry that follows a series of loops that involve planning following by acting and observing followed by reflecting. This process is self-reflective in that each new loop is based on results from the preceding cycle. The number of self-reflective loops is determined by the project. The flexible and fluid design of these projects is well suited to qualitative research methods.

Beginning a C-BAR project first involves establishing a relationship with a community. Sometimes the counselor-researcher is hired as a consultant, but usually these partnerships develop from an association between the counselor-researcher and a social agency or group. For example, a counselor-researcher who has an affiliation with a domestic violence clinic, a special needs group, or a legal aid program may eventually form a C-BAR partnership. Once this relationship is forged, the problem is defined and clarified by the community; goals and methods are selected and then implemented, and the problem-solving intervention is evaluated. The end of this sequence, evaluation, simultaneously begins the next cycle, replanning.

Conceptually, this process is simplified by an action research spiral:

PLAN → ACT & OBSERVE → REFLECT

In this spiral, C-BAR researchers take on many roles, including those of observer, reporter, colearner, and collaborator in which they facilitate community empowerment. The self-reflective element is critically important, because it allows for more effective interventions at each new cycle.

To empower community voice, the project results must be disseminated. This may represent a departure from traditional research. Rather than publishing only in professional journals, the C-BAR researcher will also make results known to policymakers, the media, popular or specialty magazines, and to whoever else can best use the information.

## Counseling and Counseling Psychology

Because it is a newcomer to counseling and counseling psychology, C-BAR's use has been limited. Generally, counselors and counseling psychologists have viewed their proper role as that of being therapists or scientists, believing community-based projects and advocacy were better suited for social workers. However, some scholars maintain that a social justice agenda is simply a return to counseling's roots, beginning with Frank Parsons.

There is a growing momentum supporting C-BAR in counseling and counseling psychology. In the past decade, professional counseling journals have dedicated entire issues to exploring counselors' emerging role as advocates for social justice. In academia, a growing number of counselors and counseling psychologists are calling for social justice agendas within training programs and practice settings. Some even suggest that APA guidelines for multicultural competence mandate an ethical responsibility to practice C-BAR. Asserting that multicultural competence must entail social justice, progressive training programs are moving to expand the traditional roles of counselors and counseling psychologists. This philosophical shift may necessitate role reconciliation to bridge the gulf between the-counselor-as-healer-scientist and the-counselor-as-social-change-agent ideologies.

C-BAR projects are carried out in a variety of settings. In a Chicago-based teen smoking prevention effort, teenagers contributed information that led to legislative changes and a police crackdown on selling tobacco to minors. In another project aimed at teens, the agency itself was the primary community and collaborated with researchers to develop sex education and pregnancy prevention interventions for at-risk youth. In yet another endeavor, researchers collaborated with clergy and parishioners to facilitate the congregations' ability to absorb an influx of immigrant members. These examples illustrate the basic principles underlying C-BAR projects. The collaborative partnerships and sharing of power were evidenced by each community's input in defining their problems and implementing solutions. Community empowerment was achieved through enhanced education, opportunity, or ability to act on their behalf.

The emerging utilization of C-BAR in counseling and counseling psychology promises both challenges and opportunities. C-BAR proponents may be initially

viewed negatively by others in counseling and counseling psychology due to their philosophical and methodological shifts encouraging community involvement and empowerment. Concerns range from objections to C-BAR's social and political overtures to questions about its academic validity and scientific rigor. C-BAR researchers may also encounter difficulties with human subject protection committees; however, these obstacles may be overcome by educating those responsible for ethical review about C-BAR. A specific opportunity for C-BAR is that some funding sources want to support projects that are based on collaboration with the community. C-BAR offers counselors and counseling psychologists expanded professional opportunities to use their skills to promote problem solving and personal empowerment at the community level.

## COMMUNITY-BASED HEALTH PROMOTION

---

Health is having quality of life in the physical, emotional, social, cognitive, and spiritual realms. The diseases that pose the most threat to achieving that quality of life are cardiovascular diseases, cancer, and diabetes. The factors that contribute to these diseases are integrally intertwined with the community and deeply connected to culture. Poverty, inadequate education, crime, and unemployment weaken the community, and these factors are associated with a higher prevalence of disease and higher mortality rates from diseases. The human and economic costs affect everyone, and these costs are soaring.

Yet, the factors that exacerbate disease are preventable or modifiable. Some factors are personal habits: smoking and chewing tobacco, overeating, sedentary lifestyles, and high consumption of polyunsaturated fats and sugars. Some factors are contextual: school-based soda vending machines, limited and overpriced healthy food choices in inner-city grocery stores or the lack of grocery stores in inner-city neighborhoods, unsafe streets that make walking dangerous, lack of adequate exercise facilities in rural areas, discriminatory practices toward minorities within the medical system, and the lack of insurance coverage for early detection of disease. Others emerge from culture-bound beliefs that inhibit health behavior change: language barriers, lack of engagement in preventive health practices, fatalism, use of emergency

rooms as primary care facilities, inability to meld the medical system to the cultural beliefs of minorities, and attitudes toward certain behaviors, such as the link between smoking and status within a subculture.

Some community factors can be changed through advocacy efforts and community awareness. For example, many school systems in America are introducing higher nutrition standards for their lunch programs. The personal factors can be changed through personally engaging interventions and community support. Efforts, however, must be stepped up to develop and test culturally sensitive strategies for health promotion. Community health promotion is proceeding along two directions. One direction is toward more individualized interventions; the other toward reaching greater numbers of people, specifically, the underserved and minorities. The challenge we face today is their integration: accomplishing a wider reach while individualizing interventions to improve effectiveness.

The diseases that carry the highest costs are caused or exacerbated by poor diet, obesity, and smoking. Therefore, this entry synthesizes the research on those practices that are likely to have the greatest impact on health.

### Smoking Cessation

Although social policy changes and media campaigns have reduced the rate of smoking in subsets of the population, smoking remains the single most preventable cause of serious illness. Despite tremendous efforts to develop and test efficacious smoking cessation treatments, only 10% to 28% of smokers achieve long-term cessation. Most treatments have been aimed at higher socioeconomic levels, yet smoking is more prevalent among those with low socioeconomic status. African Americans have higher rates of smoking, experience higher rates of tobacco-related diseases and at younger ages, and are less likely to receive physician recommendations to quit, and existing cessation programs do not address the differing beliefs, motivations, and patterns of smoking in minority populations.

At this juncture, successful treatment is too costly, impractical, and ineffective for widespread application. Community-based and workplace interventions have been shown to have limited effectiveness. However, these interventions typically focused on multiple behaviors rather than smoking alone. Low-intensity interventions such as physician reminders

can affect the rate of smoking by raising awareness and educating smokers, but they have fallen short of causing successful long-term abstinence. Those treatments that have been successful combine pharmacological components, counseling, education, and follow-up contacts. Most people relapse within the first week of quitting. Therefore, counseling interventions must be front-loaded, providing numerous contacts within the first week. Individual counseling, including problem solving and skills training tailored to idiosyncratic smoking triggers, along with assistance in obtaining social support, increase sustained abstinence. Proactive follow-up by the provider also increases success rates.

Several conclusions can be drawn from the research on smoking cessation interventions. First, multicomponent treatment, including counseling, follow-up, education, and nicotine replacement therapy (NRT) is most effective. Second, NRT improves success rates when combined with other treatments; however, the reported effectiveness of NRT has diminished in studies conducted since drugs for NRT became available over the counter, from an average of 45% to 9%, which is only 2% better than self-treatment. Third, tailoring the intervention to the stage of change leads to higher abstinence rates and improves relapse prevention. Fourth, traditional counseling approaches alone, such as cognitive-behavioral mood management, do not boost the efficacy of a multicomponent treatment program. However, applications of specific counseling interventions are beginning to show promising results. These include motivational interviewing, treatment matching to degree of dependence, contingency management, and community reinforcement. Fifth, the creative use of technology is a promising method to reach more smokers and intervene in real-life situations. One example is the use of text-messaging reinforcers on cell phones and computer-tailored smoking cessation programs.

## Obesity

Over two thirds of Americans are either overweight or obese, costing \$117 billion in tax dollars and life years lost. In the United States, minorities including Hispanics, African Americans, and Native Americans are particularly affected. Obesity is a factor in diabetes, coronary artery disease, hypertension, degenerative joint disease, gallbladder disease, and certain cancers.

Weight reduction—whether pharmacologic, surgical, or behavioral—seeks to alter energy balance. Obesity treatments focusing on altering dietary intake result in 3% to 10% weight loss, but dropout rates average 58%, and fewer than 5% keep the weight off. The most promising treatments are behavioral, resulting in 5% to 20% weight loss and dropout rates of 20%; however, most people benefiting from these treatments return to baseline weight within 5 years. Not only is such nebulous success questionable, but gain-and-loss cycling is actually dangerous.

Behavioral treatments have been the most studied and provide the fewest barriers to implementation in a community setting. The goal of behavioral treatment is to help obese patients identify and modify eating, activity, and thinking habits that contribute to their excess weight and typically yield a 10% reduction in body weight during the first 6 months. Self-monitoring (i.e., keeping records of food intake) is the strongest correlate with weight loss in both short-term (12 weeks) and long-term (17 months) studies. Studies conducted over the past decade indicate that continued contact between the patient and the practitioner significantly enhances weight maintenance, and without continued contact, patients generally regain one third of this weight within 1 year.

Perhaps due to the ineffectiveness of most dieting interventions, nondieting and size acceptance build a foundation for a healthy lifestyle of exercise and healthy eating. In uncontrolled trials, the lifestyle approach has resulted in significant improvements in self-esteem, mood, and eating-related psychopathology, and these gains have been maintained for up to 2 years. Some studies show weight loss; others, weight gain.

The addition of individual behavioral counseling to the nondieting approach resulted in significant weight loss in morbidly obese women and as adjunctive therapy. In a study comparing CBT and size acceptance versus CBT and a diet-driven program, obese women in both groups demonstrated significant but modest weight loss, psychological improvement, low dropout rates, and cardiovascular improvements. Self-monitoring, stimulus control, cognitive restructuring, problem solving, goal setting, positive reinforcement, relapse prevention, nutrition education, and coping strategies for healthy eating were used in this multicomponent intervention. Promoting physical satisfaction resulted in improved weight loss maintenance. Psychological

improvement in mood and self-esteem is instrumental in maintaining weight loss, and coping distinguishes dietary temptations from dietary relapses. Strategies that result in enhancing restraint are the most effective in weight loss maintenance.

Not every person requires all the components of a multicomponent intervention, and using a stepped-up approach that matches treatment intensity to the patient's need is more cost-effective. Motivational interviewing techniques decrease dropout rates from weight loss programs.

The majority of interventions have been individual due to the fact that community interventions lack the intensity required for weight loss and maintenance, yet community efforts, such as faith-based programs, have been used most with minority populations. Tailoring interventions to the culture is essential.

### **Sedentary Lifestyle**

The lack of physical activity is implicated in the four leading causes of death in the United States: heart disease, stroke, cancer, and diabetes. While television and electronic media constantly flood the public with promotional offers of gym memberships and popular articles on the vital role exercise plays in physical health and mental well-being, according to the American Heart Association, as of 2006, more than 24% of Americans were completely sedentary. In 2004, Americans spent more time watching television and movies than on sports and any other leisure-time physical activity combined. A recent survey by the American College of Sports Medicine found that 50% of Americans who commenced exercising in the past year have discontinued exercise.

Efforts to increase physical activity levels of Americans have been moderately successful. Those demonstrated to be effective are often time- and labor-intensive and require attendance at an exercise center, expensive equipment, and competent staff supervision. Consequently, there is a need for efficient and cost-effective methods for increasing physical activity for a diverse population within the United States. The Centers for Disease Control and Prevention notes that educational efforts alone have been ineffective in changing health behavior.

Many of the exercise interventions have been conducted with community groups; however, it would be misleading to suggest that the interventions are

homogeneous. Most are tailored to different levels of motivation, physical condition, and cultural background. Tailored messages are based on the assumption that people respond differently to message presentation based on personal characteristics. Studies using tailored messages resulted in significant improvement in various health behaviors, ranging from 74% in improving health behaviors to 91% in intent to improve.

Interventions accommodating individual stages of change have resulted in increased exercise and long-term maintenance. Results of tailored-message outcome studies resulted in better health outcomes in both White and minority populations. Studies on ethnic minorities suggest that not only should material be culturally sensitive, but it should also be individually focused in order to have a greater impact. Several factors have emerged as predictors of adherence to an exercise program in ethnic minority communities; these include age, weekly caloric expenditure incurred from doing yard work, and a sense of community affiliation as well as preexisting level of fitness and concerns about health.

Behavior-based interventions in exercise adherence have produced mixed results and seem to be more efficacious when combined with financial incentives, telephone and e-mail reminders, and personal trainers. However, behavior-based interventions have been successful at isolating predictors of long-term adherence, such as higher existing fitness levels, perceived stress, lower education, life events, body mass index, exercise program format, cognitive functioning, and male gender.

Yet, change in exercise occurred in less than 20% of the participants, and the changes rarely reached significance. There is some evidence that control is an important issue in adherence to an exercise program. Researchers found that patients' attitudes and perceived behavior control provide the strongest influence on adherence when participation was more volitional, during the latter part of a cardiac rehabilitation process, as opposed to when their participation was more compulsory, during the earlier part of the rehab program. Furthermore, self-monitoring often produces dramatic results. Telephone counseling has been shown to increase adoption of physical activity, while both telephone and "snail mail" have been shown to be effective in maintaining exercise adherence in older adults, and telephone and e-mail

reminders have been shown to be effective in maintenance of physical activity. Self-efficacy has also been shown to improve exercise adherence.

Among the more promising efforts to improve exercise in the community are those that use technology. Computerized interventions are effective for increasing physical activity through self-monitoring and reporting. Using e-mail reminders increased adherence to a walking program to increase physical activity and make small, cumulative changes in food choices. At the 12-month follow-up point, Internet participants had increased daily steps by 2,021 over the baseline, while control participants had decreased steps per day by 38. In another study on rural Caucasians and inner city African Americans, those who used the system more frequently increased exercise significantly and demonstrated greater exercise capacity after 8 months. Yet another study, which examined the effects of music, television, and combined entertainment on exercise adherence, showed that a distraction through entertainment from the physical discomfort of exercise tended to foster adherence.

Whereas a sedentary lifestyle remains problematic and posits great health risks to the American population, emerging trends in behavioral medicine suggest that the utilization of individually tailored messages, communication technology such as telephones and e-mail, and cultural considerations that take into account the ethnic, religious, and racial background of the participants can contribute to the overall health and wellness of the American population. When coupled with psychoeducational interventions, community support, and behaviorally based interventions that target health beliefs and self-efficacy, these multifaceted interventions have the potential to improve health across all of its dimensions.

*Healthy People 2010* challenges Americans to reduce lifestyle-related diseases. This is a formidable task. Despite a concerted search for solutions to the problems of adherence and maintenance of exercise, weight loss, and smoking cessation, the epidemic continues. Data from numerous studies consistently indicate that efforts must be made on all fronts—individual, social group, and community—in order to reach this goal.

## COMPULSIVE SEXUAL BEHAVIOR

---

Compulsive sexual behavior (CSB) is characterized by inappropriate or excessive sexual thoughts or behaviors that lead to stress, are overly time consuming, or lead to interpersonal, family, marital, financial, or legal problems. It appears to be widespread, to preferentially affect men, and to have an onset early in life. Psychiatric comorbidity is common, and while its cause remains unclear, CSB probably results from multiple factors. There is little consensus on treatment, but individual psychotherapy, cognitive-behavioral therapy, and 12-step programs may be helpful. Selective serotonin reuptake inhibitors (SSRIs) may help patients regulate their sexual impulses, while testosterone-reducing agents may help control sexual

aggressiveness. Additional studies are needed of subjects with CSB using standardized and reliable instruments as are careful treatment studies involving blinded assessments and placebo controls.

## Characteristics

Compulsive sexual behavior is not listed in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV)*, although many of its manifestations would fit criteria for various paraphilias such as pedophilia, voyeurism, exhibitionism, or transvestic fetishism. German psychiatrist Krafft-Ebbing described “pathological sexuality” over 100 years ago and wrote of a condition not unlike today’s CSB, in which a person’s sexual drive is abnormally increased. Various terms have been used to describe this condition, most pejorative, such as *nymphomania* and *satyriasis* in women and men, respectively, while men with this condition are frequently referred to as a “Don Juan” or “Casanova.” More neutral terms include *compulsive sexual behavior*, *sexual addiction*, or *hypersexual disorder*. It is unresolved whether this condition falls within an obsessive-compulsive spectrum of disorders, is related to addictive disorders, or represents an impulse control disorder.

The prevalence of CSB in adults is estimated to range from 3% to 6% and is thought to predominately affect men. Onset appears to be in the late teens or early 20s. Gender differences include its symptom presentation: Among men, the disorder predominately involves promiscuous sexual behavior, compulsive masturbation, or a paraphilia. Among women, the disorder is thought to involve cognitive or emotional states resulting in dangerous sexual encounters or multiple unsuccessful love relationships. CSB has been described as involving nonparaphilic behaviors (i.e., conventional sexual behaviors carried to an extreme) or paraphilias (i.e., abnormal or dangerous patterns of sexual arousal or behavior); some persons with CSB have both types of behaviors.

Psychiatric comorbidity is frequent, particularly of mood and anxiety disorders, substance misuse, and the impulse control disorders, including compulsive buying, kleptomania, and pathological gambling. Axis II (personality) disorders are also frequent, and in at least one study, 83% of persons with CSB met criteria for one *DSM-IV* personality disorder. No particular personality type predominated, though it has been

observed that persons with CSB often exhibit narcissistic, borderline, dependent, or antisocial traits.

The natural history of CSB has not been well characterized, but it is likely chronic or recurrent. It has been described as beginning in adolescence with sexual preoccupations. The next stage, often referred to as ritualization, occurs when the person develops an idiosyncratic routine that prompts the sexual behavior. The third stage consists of the uncontrollable sexual behavior itself. The fourth stage is characterized by feelings of despair and hopelessness.

Persons with CSB are secretive about their disorder, which can lead to social isolation. In addition to social and interpersonal problems that develop as a result of CSB, the disorder can lead to marriage and family-related problems, work impairment, or financial and legal consequences. In some cases, CSB can lead to genital injury, sexually transmitted diseases, and unwanted pregnancies, or even the complications of abortion.

## Cause

The cause of CSB is unknown, although developmental, behavioral, neurobiologic, and sociocultural mechanisms have been proposed. Early theorists focused on intrapsychic conflicts and environmental traumas. For example, Fenichel wrote that hypersexuality was prompted by unconscious incestuous wishes that lead to a futile search for the ideal sex partner. Contemporary theories continue to be driven by psychoanalytic views regarding the effect of abusive childhood experiences that lead to low self-esteem, anxiety, and feelings of shame. In this schema, CSB develops as a means of coping with uncomfortable affects. Learning theory has been invoked by behaviorists who argue that behavioral completion mechanisms create the drive for what becomes habitual behavior.

There are no family studies of CSB, but at least one uncontrolled survey of “sex addicts” suggests that first-degree relatives often suffer from substance misuse, CSB, eating disorders, or compulsive gambling. In a small family history study of pedophilia, which may be relevant to CSB, it was reported that this disorder runs in families (19% of pedophiliacs had relatives with the same disorder vs. 3% of controls).

A monoamine theory of paraphilic disorders has been proposed invoking dysregulation of the neurotransmitters serotonin, dopamine, and norepinephrine. The theory is based on the fact that these monoamines

play a modulatory role in regulating sexual motivation and behavior, and that drugs that enhance serotonin neurotransmission seem to reduce sexual arousal and increase behavioral control. Neuropeptides (e.g., gonadotropin-releasing hormone [GRH]), and the androgenic hormones have also been suggested as having a role in CSB, because they are involved in human sexual behavior and have been successfully used to treat paraphilias.

Cultural concepts are also relevant in that sexual behavior occurs in a societal context; one must keep in mind that our notion of appropriate sexual behavior is constantly evolving. For example, pornography is widely available throughout the United States, though in the past it was considered illegal and its purveyors criminal.

### Diagnosis

The assessment of CSB begins with its recognition, although many patients may not discuss the problem unless asked; others will seek help specifically for the disorder, or at the behest of a concerned spouse, friend, or an attorney or law enforcement officer. Persons who acknowledge being sexually preoccupied or overactive should be questioned about the extent of the preoccupation and behavioral excess. Distress or impairment related to the problem should be explored. The clinician needs to distinguish normal sexual behavior from CSB, although it may sometimes be difficult to draw a clear distinction. For example, a patient may masturbate 2 or more times daily, yet report no impairment from the behavior.

Clinicians should be aware of the wide variation in sexual drive and that no specific number of orgasms can be used to describe when the behavior is “excessive” or constitutes CSB. Clinicians should also be aware of the differences in frequency of orgasms reported by men and women and understand that frequency generally declines with advancing age. Careful judgment needs to be exercised in assessing CSB so as not to mislabel a person’s behavior as pathological because it may conflict with the clinician’s view of what constitutes normal behavior. In some persons, a physical examination and neurologic examination will need to be done to rule out medical causes. Rarely, hypothalamic disturbances, brain tumors, or temporal lobe epilepsy will be the cause of inappropriate sexual behavior. Drugs of abuse, such as psychostimulants (e.g., cocaine) can cause hypersexual behavior. The

manic phase of bipolar disorder is well known to cause temporary hypersexuality, and some psychotic disorders and dementing illnesses can also cause inappropriate sexual behavior.

### Treatment

There are no standard treatments for CSB. Individual psychotherapy is often recommended, its purpose being to provide accurate information about sexual behavior and help patients understand their disorder. The goal is to assist patients in learning more appropriate ways to express their sexuality and to meet their intimacy needs. Group therapy models have also been developed that may be beneficial in confronting the patient’s defensive lies as well as in sanctioning one another’s acceptance of more appropriate sexual behavior. A 12-step program, Sex Addicts Anonymous, similar to its sister programs Alcoholics Anonymous and Gamblers Anonymous, is helpful to some persons. Self-help books are also available. Because CSB can damage marital relationships and family ties, treatment may need to include the spouse or partner and sometimes the entire family. If substance misuse appears to be promoting or fostering CSB, then that should be a focus of treatment as well. Comorbid psychiatric disorders need to be addressed.

Medications have also been used to treat CSB, including SSRIs and antiandrogenic agents. The SSRIs are well tolerated and appear to reduce sexual preoccupations and impulsivity. Case reports and open label studies of SSRIs suggest that these agents are effective, but there have been no randomized, controlled trials. Other antidepressants have also been used in small open-label studies and may be effective. In one case study, a patient with CSB was treated successfully with naltrexone, an opiate antagonist. Testosterone-reducing agents, such as medroxyprogesterone, have been used mainly to control sexually aggressive forms of CSB, though there have been no controlled trials of these agents. A controlled trial of the GRH analog triptorelin in men with severe paraphilias suggests that it is effective.

## CONDUCT DISORDER

---

Conduct problems in children and adolescents are among the most common referrals to mental health agencies and are a leading cause for concern among family, social, and legal systems in the United States. Conduct problems can be defined as externalizing behaviors that are oppositional, defiant, aggressive, and/or antisocial, including verbal or physical violence, threatening or bullying, destruction of property, and other delinquent acts. The *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision*, (*DSM-IV-TR*), classifies problems of conduct in the broad category of Disorders Usually First Diagnosed in Infancy, Childhood, or Adolescence. The disorders attention deficit/hyperactivity disorder (AD/HD), oppositional defiant disorder (ODD), and conduct disorder are included in the subcategory Attention-Deficit and Disruptive Behavior Disorders.

### The Nature of Conduct Disorder

Conduct disorder, as defined by the *DSM-IV-TR*, is a persistent and recurring pattern of behavior in which an

individual violates the basic rights of others or major age-appropriate societal norms or rules. It is important to note that although behaviors such as lying, aggression, and defiant behaviors occur throughout typical childhood development, the behaviors that are associated with conduct disorder significantly interfere with social, academic, or occupational functioning of the individual and are more severe than those associated with normal developmental stages. The behaviors associated with conduct disorder are categorized into four main groups: aggression toward people and animals, destruction of property, deceitfulness or theft, and serious violations of rules. In order for an individual to be diagnosed with conduct disorder, three or more of the following criteria must have been met within the past 12 months, and at least one must have been present in the past 6 months: (1) often bullies, threatens, or intimidates others; (2) often initiates physical fights; (3) has used a weapon that can cause serious physical harm to others (e.g., a bat, brick, broken bottle, knife, gun); (4) has been physically cruel to people; (5) has been physically cruel to animals; (6) has stolen while confronting a victim (e.g., mugging, purse snatching, extortion, armed robbery); (7) has forced someone into sexual activity; (8) has deliberately engaged in fire setting with the intention of causing serious damage; (9) has deliberately destroyed others' property (other than by fire setting); (10) has broken into someone else's house, building, or car; (11) has lied often to obtain goods or favors or to avoid obligations (i.e., cons others); (12) has stolen items of nontrivial value without confronting a victim (e.g., shoplifting, but without breaking and entering; forgery); (13) often stays out at night despite parental prohibitions, beginning before age 13 years; (14) has run away from home overnight at least twice while living in a parental or parental surrogate home (or once without returning for a lengthy period); and (15) is often truant from school, beginning before age 13 years.

There are generally thought to be two types of conduct disorder: childhood-onset and adolescent-onset. The childhood-onset type occurs when the characteristics of conduct disorder begin prior to age 10; in the adolescent-onset type, symptoms occur after the age of 10. (Note: An individual who is 18 years or older may be diagnosed with a conduct disorder as long as criteria for antisocial personality disorder [APD]—a pattern of disregard for and violation of the rights of others occurring since age 15—are not met.) The presentation of conduct disorder in children or

adolescents is multifaceted in terms of the number and types of symptoms, the risk factors and protective factors associated with the individual, and in the degree of severity of the behaviors.

### Prevalence and Comorbidity

The prevalence of conduct disorder ranges from 1% to 10% of the general population and about 26% in the clinical setting. More specifically, recent research has found a lifetime prevalence rate of 9.5% and a more frequent rate of occurrence in males (12%) than in females (7.1%). Conduct disorder is also more prevalent among older children and adolescents than in younger children. Conduct disorder often co-occurs with other psychological disorders, and individuals diagnosed with conduct disorder are often at risk for other problems. It remains unclear whether problems with conduct cause comorbid disorders, or whether comorbid disorders increase the risk for conduct disorder; however, links have been found between conduct disorder and many comorbid disorders. For example, children with conduct disorder often exhibit AD/HD symptoms such as impulsivity and hyperactivity; however, children diagnosed with AD/HD behaviors do not necessarily engage in severe antisocial behaviors. Often, the presence of AD/HD symptoms seems to trigger problems with conduct. Additional disorders associated with conduct disorder include internalizing disorders such as depression and anxiety, learning disabilities or academic underachievement, substance abuse, and adjustment disorders. Nearly half of individuals diagnosed with conduct disorder also meet criteria for another disorder.

### Assessment

The assessment of conduct problems is a complex process that requires a comprehensive psychological evaluation of the child in many contexts using multiple assessment tools and techniques. Evaluations typically involve diagnostic interviews with parents, teachers, family members, or other individuals working closely with the child. Clinical interviews with the child may also be incorporated, making note that youth do not always view their behavior as problematic or have insight about the impact their behavior has on others. Standardized behavior rating scales (e.g., Behavior Assessment System for Children, Child Behavior Checklist) and self-report measures of

behavior and personality (Minnesota Multiphasic Personality Inventory–Adolescent [MMPI-A]) are often utilized in order to gather reliable ratings of the child's emotional and behavioral problems as observed by the child and by others. Direct observations of a child's behavior in structured and unstructured settings are also an integral part of the assessment procedure. An extensive review of school, legal, medical, and psychological treatment records is recommended as well as complete background information and family history. An assessment should also evaluate the presence of comorbid conditions that typically occur with conduct disorder and should take into account the cultural context of an individual. It is essential to identify and evaluate contextual factors that influence the child's behavior patterns and functioning, including both internal and external factors.

### Course

Evidence suggests a developmental progression that occurs with conduct problems. In particular, the progression from ODD to conduct disorder and from conduct disorder to APD has been studied extensively. The criteria for ODD include defiant and oppositional behaviors toward authority figures, although symptoms are not as severe as the behaviors in conduct disorder. About 90% of children who are diagnosed with conduct disorder also meet criteria for ODD. Research suggest that ODD could be a precursor to conduct disorder, because most cases of conduct disorder have previously met the criteria for ODD, yet most individuals with ODD do not necessarily progress to a conduct disorder. A similar pattern is found with the progression from conduct disorder to APD (which is associated with a greater severity of sociopathy or violation of societal rules than in conduct disorder). Adults with APD have almost always previously met criteria for conduct disorder, and 25% to 40% of conduct-disordered children and adolescents will progress to APD in adulthood.

Accordingly, the prognosis for conduct disorder is not optimistic, and evidence suggests that over the course of the life span, conduct disorder is relatively stable. There is a particularly negative prognosis for childhood-onset conduct disorder; individuals who develop significant conduct problems at an early age continue to exhibit more severe aggression and delinquency in middle childhood and adolescence. High recidivism rates are also associated with conduct disorders.

## **Risk Factors**

A variety of risk factors are associated with conduct disorder, including both internal and external factors.

### ***Internal Factors***

Internal factors involve individual influences such as genetic and psychobiological influences and cognitive and social cognitive characteristics. Genetic and biological influences on conduct disorder have been shown to have an indirect influence on the development of difficulties in children. Heritability traits for aggression increase the possibility of antisocial behaviors in children as well as the possibility of neuropsychological and neurophysiological problems. Cognitive problems such as low IQ have been associated with conduct problems, as have deficits in executive functioning (such as AD/HD).

Social cognitive characteristics such as social-emotional functioning, or how individuals perceive their social world, have also been related to conduct disorders. Often, conduct-disordered individuals have problems with information processing and identifying social cues; they make hostile attributions or misinterpret the intent of others' behavior. These characteristics are associated with increased aggression and negative interactions with others such as parents and peers.

### ***External Factors***

External factors include family, parent, and community sources. Dysfunction in the family structure is key to the development of aggression and antisocial behavior among children and adolescents. Family dissolution, single parent homes, and large family size often put strains on the individual's environment, and this precipitates problem behaviors. In addition, the interaction between the child and parent, the overall functioning of the family, and parent characteristics are also associated with problems in conduct. Parental psychopathology (i.e., substance abuse and depression) and criminal behavior of parents are associated with increased aggression and antisocial behaviors in children. Inconsistent parenting techniques, inadequate supervision of children, and low parental involvement are characteristics of parents of youth with conduct disorders. Physical and sexual abuse is more common among the families of children with conduct disorder, which also contributes

to family violence and aggressive behaviors. Community factors contributing to conduct disorders include low socioeconomic status (e.g., poverty, high crime rates), disadvantaged school setting, and negative peer influences.

## **Treatment**

There are a variety of treatment approaches for conduct disorder, but only a few have been empirically supported. Treatments that are considered efficacious or promising are categorized into family-based, individual-based, community-based, and multicomponent interventions. Goals are to decrease conduct-disordered behaviors and to improve prosocial functioning of the individual as well as to improve family and parent interactions.

### ***Family-Based Interventions***

Because family dysfunction is considered to be one of the major contributors to delinquent behavior, treatment approaches have focused on family-based treatment. A specific type of family-focused intervention is functional family therapy (FFT). FFT is an integrative approach incorporating family systems; it considers the family as the system that is responsible for problematic behaviors rather than the individual alone. It also views the child as a part of multiple systems, including the community, school, and peer group. It involves family, behavioral, and cognitive approaches. FFT conceptualizes problem behavior as a function of the family system and identifies how the family system displays problematic behaviors. The goal of treatment is to improve family communication and interaction patterns; counselors using FFT teach problem-solving techniques in order to improve supportiveness in the family environment.

Parent management training (PMT) is one of the most effective and widely used treatments for conduct disorders. There are a variety of models that are behavioral in nature and focus on training parents to alter ineffective or inconsistent discipline strategies in order to change the child's behavior at home. Therapists work with parents to develop and implement behavior management techniques such as positive reinforcement and contingency management in order to decrease negative behavior and increase compliance. Therapy also teaches parents to identify behaviors and use strategic principles to manage

behaviors, and it provides an opportunity to practice using these techniques. Therapy also improves the parent–child interaction and reduces deviant and oppositional behaviors. PMT has been found effective for children from 6 to 12 years of age.

### **Individual-Based Interventions**

Pharmacological interventions have been used in treating attention deficit and disruptive behavior disorders and other mental health problems in children and adolescents. Although stimulant medication for AD/HD is widely supported and effective, research for psychopharmacological treatment for conduct disorder alone has not been established. Pharmacological treatment should be considered when there is comorbidity with conduct disorder.

Child-focused interventions include cognitive-behavioral therapy (CBT) approaches. CBT is a treatment model that considers and involves cognitions, affect, and behavior when treating childhood disorders. The goal of CBT is to teach coping skills, build upon strengths, provide opportunities for practicing new behaviors, and provide interventions. Examples of CBT interventions that have shown promising effects are anger management and emotion regulation, relaxation training, problem-solving skills, cognitive restructuring, and social skills training.

A specific CBT treatment program for conduct disorder is social problem-solving skills training (PSST). PSST teaches cognitive problem-solving skills in order to address the cognitive deficits in processing associated with conduct-disordered individuals. New ways to perceive and process situations are also developed through the use of role-plays and homework assignments. In PSST, the therapist teaches the client new interpersonal and problem-solving skills such as exploring how situations are perceived and brainstorming ideas to engage in alternative behaviors. PSST has been shown to reduce symptoms of aggressive and antisocial behaviors in older children or adolescents.

### **Community-Based Interventions**

Community programs address problems from a family systems perspective or incorporate individualized treatment with family therapy. Interventions include those that occur in the community, in places where the treatment occurs (i.e., hospital or correctional

facility), and in the school, the home, and with peers. Residential treatment, group homes, and foster care placements are community-based centers that also provide various treatments for conduct disorders.

### **Multimodal Interventions**

Multimodal interventions combine one or more of the above-mentioned interventions for the treatment of psychological disorders, including conduct disorders. Researchers have evaluated the effectiveness of the combination of PMT and PSST skills-based training, and results showed that a combined treatment led to changes in child and parent functioning up to 1 year after treatment. After 15 to 20 sessions, children between the ages of 7 and 13 were less aggressive and exhibited fewer externalizing behaviors.

Multisystemic therapy (MST) is another example of a multimodal intervention that has been empirically validated for treatment of serious conduct disorders. MST is based on family systems and community based theories and incorporates a milieu of different disciplines and systems in which the child is involved (community, peers, and school). MST views the family as the main focus of intervention, and therapists often work intensively with the family in their home environment. The goal is to provide parents with techniques to manage their children's behavior and provide the children with strategies for coping with their problems. MST has been associated with reducing an individual's re-arrest rate, criminal activity, and other serious offenses.

## CONFERENCES, COUNSELING PSYCHOLOGY

---

Counseling psychology was initially recognized by the American Psychological Association (APA) as a distinct discipline of the Division of Counseling Psychology in 1944 (known initially as the Division of Personnel Psychologists). Division 17, now known as the Society of Counseling Psychology (SCP), has a membership of over 2500 psychologists. There have been four major conferences in counseling psychology that have served to advance discipline-specific identity and scope of practice, coalesce practitioners and academics, and address current issues and advocacy. In addition to the four major conferences, a fifth large-scale counseling psychology conference is scheduled to be held in Chicago in March 2008. This entry reviews the goals, objectives, attendance, and outcomes of the four conferences that have occurred and the anticipated focus of the 2008 conference.

While these four conferences have been critical in the developmental process of psychology, it should be pointed out that there are two annual conferences that focus on issues relevant to counseling psychology training programs (the annual conference of the Council of Counseling Psychology Training Programs) and to practice and research in counseling psychology (the Great Lakes Conference). Additionally, counseling psychologists are very visible at the annual APA convention, producing hundreds of presentations, symposia, poster sessions, and invited presentations annually.

While the aforementioned conferences serve to advance issues and training valued by counseling psychology, the objective of this contribution is to place the four critical conferences—Northwestern, Greyston, Atlanta, and Houston—in context of the ongoing development of the unique identity of counseling

psychology. The 2008 International Counseling Conference is also included in the review.

### Northwestern Conference

An early formative occurrence in the professional development of counseling psychology was the Ann Arbor conference held in 1949 and sponsored by the University of Michigan and Division 17. This conference was funded by a public health grant and had a purpose of delineating the best plan for training counselors who planned to be psychologists. A report from the conference indicated a need for clearer distinction between clinical and counseling psychology. The Ann Arbor conference was significant in this primary agenda—to articulate the distinction between these two disciplines.

While the Ann Arbor conference was critical in the formation of the discipline, the Northwestern conference is identified as the first counseling psychology conference and had a reported attendance of 34 participants. This event was held at Northwestern University in 1951, 5 years after the discipline was recognized by the APA. Nadya Fouad and colleagues delineated three themes of the Northwestern conference; these were identity, training, and political and social advocacy. However, the ambiguity of the identity of counseling psychology was central to the conference. Indeed, it was at the Northwestern conference that the term *counseling psychologist* was selected as the name of the discipline. Additionally, Donald Super is credited with articulating the focus of the discipline on hygiene, or the preservation of health, rather than on pathology. An additional theme was the recognition of the equal emphasis on science and practice rather than the prioritization of one over the other.

Training was another theme of the Northwestern conference. At the time of that conference, only a third of the members of Division 17 held doctorates. The participants formulated recommendations to increase the rigor and uniformity of the doctoral training of psychologists, including attention to curriculum needs, clinical training sequences, and admission processes.

The third theme of the Northwestern conference was political and social advocacy. While the primary allocation of time was spent on training and identity issues, there was attention given to two primary areas of advocacy—pressing APA to recognize counseling psychology as a specialty and working with the

Department of Veterans Affairs healthcare system to develop and implement internship and practicum training opportunities for counseling psychology doctoral students.

### **Greyston Conference**

The next significant counseling psychology conference is known as the Greyston conference; it was held in 1964 and organized by Donald Super and Al Thompson. Participants, approximately 60, were invited to convene and address current issues, such as the lack of empirical rigor of scholarship, low status of the specialty, program admission selection, and differential standards in colleges of education versus liberal arts schools. The conference proceedings and recommendations were published in a book by Thompson and Super in 1964.

The Greyston conference themes sorted across identity, training, and social and political advocacy. In the area of identity, what was seen in the 1960s was a lack of distinction of the specialty; there was too much overlap with clinical psychology, guidance and counseling, and vocational counseling. Preceding the conference in the early 1960s, there was great divergence on the actual identity of counseling psychologists, even to the point that Irwin Berg, Harold Pepinsky, and Edward Joseph Shoben stated in a report commissioned by the executive board of the APA that the field was declining and should fuse with clinical psychology. However, it was concluded at the conference that there was not actually an identity issue; rather, there was a lack of visibility and limited professional activity that limited the public's and universities' knowledge of the discipline.

The training issues addressed at the Greyston conference reflected concerns regarding identity. Specifically, some worried that the focus on adjustment and preservation of health precluded a necessary understanding of pathology and diagnosis. Other concerns were the relative lack of financial support of students compared to those in clinical programs and the lack of standards with regards to training program faculty. Also, there was concern about the loss of training in vocational psychology in some programs. Training recommendations emerging from Greyston included the belief that counseling psychology training programs should be led by appropriately trained counseling psychologists. There were specific recommendations made about the sequencing of clinical

training from practica through internship. Additionally, the breadth and specificity of training as reflected in the curriculum was addressed through specific recommendations.

The political and social advocacy theme of the Greyston conference was complex, focusing on the relationship between the specialty and APA as well as larger social issues of the 1960s. Specific to APA, a focus of concern was the lack of visible understanding of the discipline, which was evident in accreditation practices and documentation. Recommendations were issued that APA take a more active role in recognizing the specialty of counseling psychology as well as disseminate information about counseling psychology and evaluate internships specific to the discipline. With regard to addressing the social change and challenges of the time, one of the recommendations was for counselors to become active in the aspects of their clients' lives that related to segregation, housing, employment, and minimum wage. At the same time, there was concern that these needs might be met by master's level clinicians rather than doctoral level counseling psychologists, a concern that prevails today. The Greyston conference did not produce a specific product; rather, it is credited with a reaffirmation of the scientist-practitioner training model and that the discipline should continue to grow and prosper.

### **Atlanta Conference**

The Atlanta conference followed in 1987 with an attendance of 180 participants divided into working groups to address five issues that were then current; these were professional practice, training, research, organizational issues, and public image.

Regarding identity issues across the period since Greyston, counseling psychology continued to struggle with identity. However, this time it was due to the proliferation of clinical psychology training programs and doctoral programs in psychology as well the movement toward generic rather than discipline-specific internships. Each of these factors was seen as a potential threat to the viability of the discipline. At the same time, counseling psychology had made significant increases in the number of accredited counseling psychology programs. The primary focus at the Atlanta conference with regard to identity was on the unique aspects of the discipline. Recommendations from the conference encouraged graduate training programs to foster a sense of identity with the discipline,

to more actively regulate the designation of counseling psychology, and to have all counseling psychologists maintain membership in Division 17.

Training issues addressed at the Atlanta conference included the strong support of the scientist–practitioner training model. Participants also reviewed the need to more fully prepare students to work with a range of clients and the realities of training programs housed in colleges of education rather than arts and sciences. The primary product of the Atlanta conference was the development of the Model Training Program, which provided an agreed-upon guide for counseling psychology training programs. There were some critics of the conference, stating the conference moved from an original endorsement of health and adjustment to one of concern with pathology.

Social and political advocacy legacies of the Atlanta conference included an increase in research and training in multicultural issues, stronger advocacy in and involvement with APA governance, and the development of special interest groups within Division 17 to increase member connection to the organization by addressing their areas of interests.

### **Houston Conference**

The Houston conference followed in 2001; it was organized by Nadya Fouad, past president of Division 17 at the time, and Robert McPherson, past chair of the Council of Counseling Psychology Training Programs (CCPTP). This conference was the largest to date with over 1000 participants, including a large number of graduate students. The Houston conference was unique in that it was the joint effort of Division 17 and CCPTP. The stated goals of the conference were (1) to identify ways counseling psychologists work toward social justice by making a difference in the lives of students, clients, and communities; (2) to share scholarly and practice advances made in the field; (3) to begin to identify new pathways for counseling psychology, and (4) to become a national voice in local and global communities.

The Houston conference did not address identity for many reasons. It was believed by many that the profession had sufficiently matured and had a clearer sense of definition. Additionally, much of the work had been accomplished with regard to definition and identity in 1999, when the Commission of Recognition of Specialties and Proficiencies in Professional Psychology (CRSPP) issued, after appropriate vetting

through the relevant professional constituencies, a description and definition of counseling psychology, defining the parameters of practice: “Within the context of lifespan development, counseling psychology focuses on healthy aspects and strengths of the client (individual, couple, family, group, system, or organization), environmental/situational influences (including the context of cultural, gender, and lifestyle issues) and the role of career and vocation on individual development.”

The Houston conference did, by comparison, spend a significant amount of time addressing training issues. The program emphasized better preparing students to address the demands of clients with higher levels of distress and pathology as well as to work within managed healthcare arenas. Additionally, trainee impairment, which had recently emerged in discussion at training forums and in the literature, was also addressed in symposia. There was discussion about various training models, particularly the scientist–practitioner and practitioner–scholar models. While there was rigorous discussion across topics, clear and cogent recommendations were not a product of this conference.

Social and political advocacy was a clear strength of the Houston conference. The development and implementation of the social action groups (SAG) represents the most thoughtful, organized, large-scale effort to prioritize social advocacy in any organized effort in counseling psychology to date. The SAG coordinators for the Houston conference were David Blustein, Nancy Elman, and Larry Gerstein. There were nine SAGs developed for the conference; they focusing on the following issues—community violence, domestic violence, child abuse and neglect, homelessness and welfare, the economic boom and the poor or working class, care for the chronically or severely mentally ill, racism, social justice and ethics in counseling psychology practice, and the moral challenge of managed care. Over 400 conference participants indicated an interest in participating in one of the SAGs, although only 77 actually attended the SAG meetings. The various SAGs produced many recommendations; they suggested that a special interest group be developed in Division 17 that addressed social justice, that a listserv be set up for individuals interested in social justice and advocacy, and that attention be given to multicultural systems and social justice in APA accreditation standards as well as in graduate training programs. In addition to the SAG

activities, the Houston conference sponsored multiple auxiliary advocacy activities, including a legislative fundraising dinner for and reception with Congressman Ted Strickland, a Houston Red Cross blood drive, and fundraising activities for earthquake victims in El Salvador.

The Houston conference is noted to be the largest to date, advancing social justice and advocacy as a core value in counseling psychology. Additionally, this conference brought the membership together with leaders from the four APA directorates, providing an opportunity for dialogue and relationship building. Approximately 40% of participants were students, and all of the counseling psychology programs in the country were represented.

### 2008 International Counseling Conference

The next major conference in counseling psychology is the 2008 conference in Chicago. The conference cochairs are Laura Palmer, past chair of CCPTP, and Linda Forrest, president-elect of SCP. The cochairs are working together with Association of Counseling Center Training Agents (ACCTA), representing a three-part model of organization and the intent to partner the three principal entities in the discipline. The steering committee comprises 13 individuals representing key positions in SCP, CCPTP, and ACCTA. Additionally, students and early career psychologists are members of the steering committee. Nine key committees have been formed; they are cochaired or trichaired by members of the three sponsoring organizations. The title of the conference, *Creating the Future: Counseling Psychologists in a Changing World*, captures the overall goal of the conference: to look at the multiple issues affecting counseling psychology locally and globally. The conference planners, steering committees, and subcommittee members are working toward integrating global colleagues into the planning and hope to host a number of counseling psychologists from many countries. Additionally, there is a strong initiative to develop a conference that will be of interest to counseling psychologists across multiple arenas—practice, teaching, research, industry—through relevant programming. The conference, like those described earlier, includes mechanisms that address identity—particularly as it applies to globalization of training, practice, research, and collaboration; training—with a focus on further

elaboration on discipline-specific competencies and the sequencing of training; and social and political advocacy, which includes training on advocacy, political speakers, and fundraising activities.

## CONFERENCES IN COUNSELING

---

Conferences in the field of counseling offer students, practitioners, researchers, and scholars opportunities to gather, interact, and learn within a larger and often diverse environment. Individuals with common interests have formed societies and convened in groups for discussion and debate since the time of Socrates. In the field of psychology, the first formal meeting of professionals was the First International Congress of Psychology held in Paris in 1889, followed closely by the founding of the American Psychological Association (APA) in 1892. In 1952, the American Personnel and Guidance Association was founded. Today, these professional societies and associations provide a forum in which members can discuss affairs and training standards of the association, participate in educational events, engage in professional renewal, strengthen professional identity, and make contacts with others who are interested in psychology and counseling.

### Conferences in Context

Professional gatherings can stimulate creative and intellectual understanding among individuals. In the United States, the first formal professional conference in psychology was held in 1892 with the founding of the APA. This association met annually for members to exchange ideas, set standards for membership, and attend to the business affairs of the association. In 1952, four independent associations joined forces in Los Angeles to discuss and organize a greater and more unified professional voice for counselors. The four associations included the National Vocational Guidance Association (NVGA), the National Association of Guidance and Counselor Trainers (NAGCT), the Student Personnel Association for Teacher Education (SPATE), and the American College Personnel Association (ACPA). These four organizations became one larger organization, the American Personnel and Guidance Association (APGA). In 1983 APGA became the American Association of Counseling and Development (AACD), and later, in 1992, the AACD changed its name to the American Counseling Association (ACA) to reflect the growing unity of purpose among its members.

Interest in the area of counseling and psychology continues to grow as evidenced by the numerous areas

of specialty and subspecialty development within the APA and ACA. Currently there are 54 divisions and 58 state or provincial associations within the APA. The ACA has 19 divisions and 56 branches. Many of these divisions and regional associations also hold annual conferences as a benefit for their members. These conferences in counseling are the organizational descendants of these associations' historic annual meetings.

### Conferences and Other Opportunities for Learning

Many professionals are committed to continuous learning and enhancement of their knowledge base and skills. Today's counselors and psychologists can seek training from a variety of sources (e.g., conferences, workshops, graduate coursework, postdegree certification, independent study) and in a variety of formats (e.g., in person, online, or hybrid). Although all of these entities provide the opportunity for an instructive experience, conferences are unique in that they (1) typically mandate that participants belong to the sponsoring organization, (2) are assumed to attract persons who share a particular vocation or professional identity, (3) are viewed as a benefit of membership, (4) provide members information regarding the financial status of the organization, (5) afford members access to the governing board, and (6) offer a place to discuss the social relevance and purpose and standards of the organization. There is, at a minimum, an implied, if not overt, agreement that the basic beliefs and purpose of the association draw individuals to attend and participate.

### The Functions of Conferences

Conferences in counseling serve both professional and personal functions for counselors. There is, of course, some overlap between these domains, as it is the intent of most associations to serve the needs of individuals by means of the organization's activities. The professional functions of conferences are characteristically related to the needs of the whole group. For example, such functions may include discussing the financial status, professional identity, mission, and legacy of the association; formulating or executing social or legislative policy; determining training and research standards; and providing the development of the next generation of leaders. The personal functions

are typically focused more on the needs of individuals and may include educational sessions, leadership training, networking, mentoring, sponsorship, professional identity development and maintenance, socialization, and conviviality.

### ***Professional Functions***

The three primary professional functions of association-sponsored conferences are financial management, articulation of a professional identity, and review of policies and procedure. These functions are administered through a governance structure, e.g., the board of directors for APA or the governing council for ACA. The officers of these governance groups are responsible to the membership at large for both the day-to-day functioning of and long-range planning for the association.

The first professional function, financial management, provides a means for the officers of the association to formally and regularly inform the membership of the financial status of the organization, which may include a review of the annual financial report, efforts at fundraising and endowments, fee and benefit configurations, and expenditures. Although most members do not participate in these sessions, an annual review of the associations' financial status is typically required by bylaws and is critical to maintaining transparency with respect to the associations' financial transactions.

The second professional function of conferences, articulation of a professional identity, provides an opportunity for the members to clarify and or strengthen the mission and professional identity of members. These two concepts are inexorably linked, as the mission of any association defines the professional behaviors and therefore identity of its members. From time to time, the governance officers of an association identify a theme or issue that is, or has the potential to be, critical to a majority of the membership. An example of this type of conference programming occurred when the counseling psychology division of the APA held four national conferences; these were at Northwestern University in 1951, at the University of Wisconsin's Greyston Center in 1964, at Atlanta in 1987, and at Houston in 2001. These four conferences, along with the APA's 1973 Vail conference, have provided a definition, mission, and training standards for counseling psychologists.

In the late 1970s the APGA (now ACA) sponsored a committee to investigate the need for a national

accrediting agency for counselors. Over a period of 2 to 3 years, representatives from the Association for Counselor Education and Supervision (ACES), the American School Counselor Association (ASCA), and other divisions met at national and regional conferences and determined that such a body was necessary and viable. This agency, the Council for Accreditation of Counseling and Related Educational Programs (CACREP), was founded in 1981 and continues today to set the educational and institutional requirements for counseling programs at the master's and doctoral levels.

As agents and advocates of change, counselors and psychologists take an active role in social and political discussions that affect their clients, profession, and general human well-being. The third professional function of conferences, reviewing policies and procedures, affords participants a wide array of opportunities and options with respect to the type and level of involvement in policies and legislation that could potentially impact the profession. Members may also focus on the internal policies and politics of the association. This type of involvement is often associated with the development of the next generation of leaders with the particular association.

### ***Personal Functions***

Conferences are a gathering of people who are seeking both professional and personal connections. The personal functions of conferences typically center on the individual's desire for educational, mentoring, networking, and socializing contacts. Participants typically attend conferences seeking some form of continuing education or enhancement of skill. Professional associations call for peer-reviewed educational sessions, papers, and workshops. National and international conferences offer a plethora of opportunities to enhance one's knowledge or learn something completely new. Many conferences offer different tracks or themes from which participants may choose. Tracking also allows persons with shared interest (e.g., research findings, new practice approaches) to focus their interests and perhaps meet other professionals with whom they may collaborate.

Conferences are a great benefit to the membership, as many members reconnect with faculty or former peers from institutions of higher learning. Most professional counselors and psychologists have received or are receiving their formal training

in these types of institutions, and many conference participants continue their affiliations with universities as either faculty or students. This affiliation provides a ready-made opportunity for mentoring and sponsorship of colleagues and students. Research findings in the area of mentoring identify a multitude of benefits derived from the personal and professional sponsorship of one's mentor in informal settings such as conferences and the socializing that accompanies them.

The personal and social contacts made during conferences can enrich the personal and professional lives of attendees. Conferences provide a setting for the exchange of ideas, information, employment opportunities, and policies. Individuals can be with subgroups of the association that may have a formal meeting or contact only once a year, or they can sample from a wide variety of areas. It is important to recognize that conferences are a blend of the personal and professional aspects of the individuals who attend that particular conference.

## CONNERS' RATING SCALES—REVISED

The Conners' Rating Scales—Revised (CRS-R) comprises a set of six standardized measures designed to evaluate behavioral symptoms of attention deficit hyperactivity disorder (AD/HD). The rating scales—each available in long and short form—are completed by teachers, parents, and adolescents. All items contained within the various CRS-R forms utilize a 4-point scale; these include 0 (not true at all), 1 (just a little true), 2 (pretty much true), and 3 (very much true). There are three methods for calculating scores. The clinician can calculate scores using an answer sheet. Alternatively, computer scoring and interpretive reports are available through the publisher. Finally, a computerized version is available that scores the rating scales and provides an interpretive report.

The standardization sample consisted of 8,000 cases, and data were collected from 200 sites in the United States and Canada. According to the manual, more than 95% of all states and provinces in the United States and Canada were included. A total of 1,000 Black adolescents were included in the sample, which—according to the manual—warranted the creation of normative data specifically for Black youth.

The standard error of measurement for the CRS-R was characterized as low. According to Conners, if individuals were assessed simultaneously, 95% of the scores would be within  $\pm 1.96$  SEM of their theoretical true scores. Similar observations were made with respect to the standard error of prediction. Clinicians could have expected an individual's obtained scores to be within  $\pm 1.96$  SEM of predicted scores.

Test-retest reliabilities were secured from samples of 49 to 50 youth; retest intervals spanned 6 to 8 weeks. Correlations ranged from .47 for the Conners' Teacher Rating Scales—Revised Long Version (CTRS-R:L) Cognitive Problems and *DSM-IV* Hyperactive-Impulsive scales to .89 for the Emotional Problems subscale of the Conners-Wells' Adolescent Self-Report Scale Long Form (CASS:L). Internal consistency reliabilities for the CRS-R Parent and Teacher Forms were within the moderate ( $r = .73$ ) to high ( $r = .96$ ) range. Likewise, the Adolescent Self-Report Form evidenced moderate ( $r = .75$ ) to high ( $r = .92$ ) internal consistency reliability coefficients.

Factor analysis used to construct the scales evidenced acceptable construct validity. Convergent and discriminant validity provided additional support for

construct validity. Convergent validity was demonstrated using correlations of long and short forms, which ranged from .95 to .99 on various scales. Discriminant validity was supported by evidence that the CRS-R discriminates between clinical and nonclinical groups.

The psychometric properties of the CRS-R demonstrated considerable improvements over the original measure. The reliability and validity estimates are generally acceptable. However, the standardization sample was not representative of the U.S. population as reflected in census data. Black parents were underrepresented; White parents were overrepresented; and the adolescent scales overrepresented Black youth. Furthermore, several reliability and validity estimates were derived from samples of 100 individuals or fewer; some included fewer than 50 observations. As stated above, the manual reported that the CRS-R significantly delineates clinical from nonclinical groups. It is noteworthy that approximately 38% of the youth within the study sample had an AD/HD diagnosis, whereas base rate estimates for the prevalence of AD/HD within the general population have been 2% and 7%.

## CONTINUING EDUCATION

---

Continuing education for individuals in the counseling professions is often required for maintenance of licensure or certification status. Agencies that offer licensing

or certification for counselors include state organizations, professional associations, and specialty or national affiliations. The term *counselors* applies to persons who are licensed or have received specialized training in mental health fields such as rehabilitation counseling, marriage and family counseling, and school counseling. Other professionals who practice counseling may include counseling and clinical psychologists, psychiatrists, psychiatric nurses, and social workers.

Continuing education is intended to promote the maintenance and development of professional competency for counselors and other professionals. Not all regulating bodies require counseling professionals to complete continuing education activities, but required continued education has become increasingly common. States and other regulatory bodies typically mandate that counselors who hold licenses or certifications demonstrate their continued competency through completing continuing education activities. Counseling professionals seeking relicensure or recertification will receive, from the agency overseeing the process, details regarding expected continuing education content and format in addition to requirements for amount and frequency of continuing education hours. Completion of the requirements within the time frame gains the counselor certification or licensure for a time period specified by the state or professional organization.

## Characteristics of Continuing Education

### Purpose

Continuing education serves to contribute to the sustained knowledge and skill acquisition of counselors beyond their terminal degree, licensure, or certification. Continuing education is referred to as both *mandatory continuing education* and as *lifelong learning*. These two perspectives on counselor knowledge and skill acquisition can certainly be related, but they represent different concepts. Mandatory continuing education is a required professional activity for counselors wishing to maintain licensure or certification. Depending on a counselor's degree or certification, continuing education is mandated by state, agency, or organizational policies. Different governing bodies require different types and amounts of continuing education activities, but in general, continuing education serves to advance and maintain a counselor's body of knowledge and skills. More specifically, mandated

continuing education facilitates continued expertise in counselors' field of study as well as awareness of new professional developments, and it protects consumers of counseling through instituting a regulated standard of minimum competencies. Lifelong learning, while an incidental effect of mandatory continuing education, can also be recognized as activities counselors engage in to augment preexisting knowledge for the purpose of personal and professional development rather than to fulfill a professional requirement. Although lifelong learning can be understood as a potential outcome of any continuing educational activity, the term *continuing education* is more commensurate with the formalized professional requirement and therefore mandatory continuing education will be the main focus of this entry.

### **Content**

The content of continuing education activities is sometimes mandated, but it is more often flexible in order to allow counseling professionals to self-select areas of interest or new specializations or skills. States, agencies, and other governing bodies often require licensees and those they certify to obtain knowledge in particular domains to enable counselors to keep their expertise current and to introduce counselors to areas of new professional development. For counselors, those domains vary considerably but can include child abuse, ethics, multiculturalism, and legal issues. Some counseling professionals may be required to access continuing education in a certain topic area for a certain period of recertification or licensure. Continuing education topics reflect the diversity within the fields of counseling and therefore have an extensive scope. For example, school counselors, career counselors, and professors in counseling education will likely choose different counseling-related education opportunities in order to tailor their continued learning. Most regulating agencies approve continuing education opportunities and content endorsed by major national organizations such as the American Psychological Association, American Counseling Association, and American Association of Counseling and Development as well as state and regional organizations.

### **Format**

Continuing education opportunities are offered through a variety of organizations, institutions, and

agencies. Continuing education activities commonly include attendance at conferences, professional meetings, and workshops; participating in professional activities such as roundtable discussions; teaching; and presenting or publishing professional work. Continuing education activities also encompass didactic activities, including specialized coursework, journal readings, and other independent study.

Literature on continuing education supports the assertion that counselors prefer to engage in local and regional workshops, readings, and independent study to meet continuing education requirements. Because continuing education costs are the responsibility of counselors, or less commonly counselors' employers, cost may be a factor in counselors' preferences for continuing education activity format. The format of continuing education may be mandated by state licensing boards or other regulating bodies. Like the content of continuing education activities, the counseling professional is often afforded a considerable amount of decision-making freedom when choosing formats that are most appropriate for accessing topics of interest or that contain required content.

### **Frequency and Amount**

Activities for continuing education are often measured in hours, credits, or units. Formulas for continuing education units often involve a ratio of continuing education units per clock hour of activity. For example, one continuing education unit may equal ten clock hours of an activity. Some regulatory groups require specified numbers of continuing education units, credits, or hours on an annual, biannual, or triennial basis; a minority of regulatory groups have specifications for continuing education to be completed within a 5-year period. All licensing or certification regulatory bodies that require continuing education specify that professionals provide evidence that they have participated in the required number of hours, credits, or units. Some agencies further specify that professionals provide an assessment of whether or not the continuing education knowledge and skills have been learned. Common assessments include a content-specific measure, feedback from a workshop presenter, or reflective comments about the activity.

The amount and frequency of continuing education required varies for professionals within the counseling fields. Because state licensing agencies hold different specifications for continuing education

requirements that may differ from a professional's national affiliations, counselors must work to meet requirements for continuing education for their professional affiliations and their state licensure. There is much variability in the requirements themselves as well as in how professionals choose to meet them. For example, the National Board for Certified Counselors requires 100 hours of continuing education to be accrued within a 5-year period, and the National Association of Social Workers requires that professionals attain 90 hours of continuing education within a 3-year period. Alternatively, the majority of states require psychologists to document participation in 20 to 40 hours of continuing education every 2 years. Despite the range of continuing education requirements across professions within counseling, each governing body requires specific educational activities within a stated time frame for the professionals that the body continues to license or certify.

### Current Trends and Future Directions

With the increased prevalence of mandated continuing education, counseling professionals have begun to discuss its impact on fields within counseling. Regulatory bodies and counselors have raised questions about whether or not continuing education should be mandatory, whether continuing education is effective, and whether counselors participate in continuing education activities without a requirement. Discussion has also been raised regarding the disparity between the concept of lifelong learning and mandated continuing education. Proponents in favor of lifelong learning argue that counselors should engage in professional activities and learning opportunities for their own professional and personal development rather than to meet a general requirement. Future research, theory, and discourse will continue to refine the way in which continuing education is used to ensure quality service provision to consumers, teach professionals about new developments within their field, and prevent decline of professional knowledge and skills.

## CONTINUOUS PERFORMANCE TESTS

---

The continuous performance test (CPT) is one group of measures for the evaluation of attention as well as response inhibition (or disinhibition); Fleming, Goldberg, and Gold have described the CPT as the gold standard for measuring sustained attention. The original CPT was developed by Rosvold, Mirsky, Sarason, Bransome, and Beck in 1956 as a research tool to study vigilance. Since that time, the CPT has continued to be used in the study of attention as well as executive control, with multiple variations in the components of the task; today, the majority of CPTs are computer administered.

### Basic Paradigm

The basic CPT paradigm consists of rapid presentation of continuously changing stimuli with a designated “target” stimulus or pattern such that the individual is to respond (or inhibit responding) based on the stimulus presented. It requires selective attention or vigilance for an infrequently occurring target

or relevant stimulus; at the same time, the duration of the task is intended to be sufficient to measure sustained attention. Despite these general similarities, there have been as many versions of the CPT available as there were clinicians who used them. Different CPTs include variations in the basic task (i.e., when to respond or inhibit), the characteristics of the target, variations in the interstimulus interval (ISI), presence or absence of distracters, modality of presentation, duration of the target presentation, duration of task, and so on. The effects of some of these possible variations and modifications to the CPT on performance have been reviewed elsewhere.

### Variables of Interest

CPT variables reported include correct hits (number or percentage of correct responses to targets) and omission errors (i.e., number or percentage of targets not responded to). Both correct hits and omission errors are interpreted as indicative of selective attention or inattention. Commission errors (number or percentage of responses to stimuli other than the target) are reported as an index of response inhibition or disinhibition. In some studies, relative accuracy (percentage of correct responses) or total errors (combining omission and commission errors) may be reported.

Reaction time is another measure frequently reported with CPTs. Reaction time or response latency is believed to reflect the speed of processing as well as the speed of motor responding. For example, a child may demonstrate increased omission errors and a slower rate of responding without an associated increase in commission errors; this type of pattern may be interpreted as supporting a hypothesis of difficulty with the allocation of information-processing resources. The consistency or variability of the individual's performance over time is also of importance; some CPT programs generate the standard deviation of the reaction time across blocks as a measure of consistency in responding and of the ability to sustain attention over time. Alternatively, some researchers report the standard error of the reaction time as an indicator of the consistency or variability of responding over time. Still others use the standard deviation of the standard error over time as an indication of consistency. Rather than using differences in the reaction time as a measure of consistency, some clinicians focus on comparisons of correct and

incorrect responses over differing blocks of time within the same administration (i.e., vigilance decrement).

As an alternative to direct performance scores, some clinicians incorporate signal detection theory (SDT) in generating performance indexes for interpretation. The basic premise of SDT is that the decision to respond is based on the child's setting a certain standard or criterion for responding. SDT variables of sensitivity (also referred to as  $d'$  or  $d$ -prime) and response bias (also referred to as  $\beta$ ) are based on signal to noise (i.e., target to nontarget) ratios. Lam and Beale argued that the sensitivity and bias indexes may be more sensitive to differences in performance on the CPT than omission or commission errors and that SDT procedures may be particularly useful in neuropsychological assessment.

### Technical Adequacy

Ethical and professional standards demand that clinicians use measures that are technically adequate. With CPTs, as with any formal assessment measure, it is important for administration to be standardized consistent with the collection of normative data. As such, it is imperative for the CPT manuals to clearly state the conditions for standardized administration. Ballard reviewed a number of experimenter-manipulated variables that may influence CPT scores and recommended that manuals address these issues (e.g., examiner presence or absence, instructional set). The potential for these changes to affect test performance, possibly invalidating the interpretation of the results, requires adherence to standardized procedures in the administration of any CPT. In addition, given differences in task demands and parameters across CPTs, performance on any one of these CPTs can be interpreted only based on the normative data for those specific task parameters. For these reasons, although the capacity to customize the task may be beneficial for research purposes, clinical use of customized CPTs is not recommended due to the lack of normative data.

### Use and Interpretation

Clinicians also need to be cautious in their interpretation of CPT results. The CPT is only one measure, and multiple sources of information and multiple measures should be used when assessing attention and impulse control problems in order to corroborate CPT findings. Taken together with direct observation,

behavior rating scales, and other psychometric tests, the CPT may provide useful information. The CPT is an objective measure that is not subject to rater bias or observer drift; as such, the level of performance on CPTs may be helpful in ruling out or identifying attentional problems and for monitoring medication effectiveness. However, reliance on CPTs as a primary diagnostic tool in determining the presence of a specific disorder (e.g., attention deficit hyperactivity disorder [AD/HD]) is not warranted and will result in an unacceptably high number of false positive errors or overdiagnosis of AD/HD. Without evidence of both internal consistency and temporal stability, any conclusions related to diagnostic considerations or treatment effectiveness are questionable. Given all of the possible variations to the CPT paradigm, it is possible that some combination(s) will prove more helpful in differential diagnosis than others.

---

## CONVERSION THERAPY

---

Conversion therapy (also known as reparative therapy, reorientation therapy, or transformational therapy) has been generally understood to have as its chief goal the cessation or changing of individuals' same-sex attraction and sexual behavior and the adoption of opposite-sex attraction and sexual behavior. Proponents and practitioners of conversion therapy base the rationale for such intervention on medical, moral, or religious traditions that regard homosexuality and homosexual behaviors as unnatural, psychopathological, or morally transgressive.

However, since the 1970s, mainstream mental health organizations (American Psychiatric Association, American Psychological Association) have adopted nosology and policy that reject the idea that homosexual individuals are mentally unhealthy simply because of their sexual orientation. Beginning in the late 1950s, scientific research such as that generated by Evelyn Hooker clearly demonstrated that homosexuals do not suffer any greater frequency of psychopathology than heterosexuals and that common psychodiagnostic tests cannot identify or effectively discriminate between homosexuals and heterosexuals.

In addition, the American Psychiatric Association, American Psychological Association, American Academy of Pediatrics, American Counseling Association, and National Association of Social

Workers have all adopted professional positions that oppose conversion therapy, citing as problematic its portrayal of homosexuals as abnormal, its almost exclusive focus on changing homosexual men while ignoring lesbian women, a lack of scientific support for its effectiveness, questionable ethics underlying such interventions, and the iatrogenic dangers (depression, anxiety, and other disorders) inherent in trying to persuade homosexual individuals that they are “ill” or in need of a “cure.”

### **What Is Conversion Therapy?**

Conversion therapy encompasses a range of techniques and approaches; many distinctions among them are dependent upon the underlying philosophy of the practitioner. Early psychological techniques of conversion therapy focused on long-term, classical psychoanalysis that sought to uncover and provide corrective emotional experiences for theorized Oedipal traumas thought to have arrested sexual development and caused homosexuality. Other approaches have utilized behavioral techniques, seeking to condition an aversion in homosexual individuals to same-sex activities by pairing homoerotic stimuli with unpleasant experiences (electroshock, anxiety, nausea). Some approaches take the form of verbal therapy or counseling, focusing on thoughts, feelings, and behaviors associated with homosexuality and teaching avoidance of these experiences.

Conversion therapy based upon religious traditions often relies on practitioners utilizing interpretations of religious doctrine or texts that forbid and condemn homosexuality; such practitioners seek to help homosexual individuals correct or cease sexual behavior that is found outside what is acceptable according to these doctrines. Such transformational ministries and “ex-gay” ministries (e.g., Exodus International) focus upon homosexuals’ inner turmoil as they attempt to reconcile their chosen religious or spiritual belief systems with their homosexuality.

Many proponents of conversion therapies hold the position that if a homosexual views his or her sexual orientation as unhealthy or as being against personally held beliefs and wishes to convert to heterosexuality (or at least stop same-sex sexual practices), that person has a right to such self-determination and a right to seek treatment to achieve that goal. However, research on sexual identity development suggests that because of societal heterosexism and the inculcation

of antihomosexual and proheterosexual attitudes into our society, it is a part of normal identity development for homosexual persons to experience a strong sense of confusion, fear, doubt, denial, stigma, and even self-hate surrounding their homosexual attractions. If “coming out” (the process of fully realizing and accepting one’s homosexuality) is met with supportive and positive social reactions, this initial difficult phase of identity development can give way to a healthy self-concept and positive self-identification as a homosexual.

### **Does Conversion Therapy Work?**

No program of peer-reviewed research published in mainstream scholarly journals shows that conversion therapy is effective. Those studies that have been conducted are often plagued by sampling problems that make drawing conclusions very difficult. For example, if an investigator examines the efficacy of conversion therapy with a sample of bisexual men (who have sex with persons of both the same and opposite sex), the ability of the men in this study to cease having sex with men for a period of time may be very different than would be found in a study where conversion therapy was provided to men who were strictly gay. As well, operationalization of what constitutes an “effective” outcome has been difficult. For example, the cessation of engagement in same-sex sexual relations is often considered a measure of “successful” conversion therapy; however, it is highly unlikely that behavioral cessation has also fundamentally changed the actual homosexual orientation of clients, who still emotionally and sexually desire same-sex persons and attitudinally think of themselves as homosexual. This latter state of affairs is anecdotally reported by “ex-gays” who have received conversion therapy. Many either have chosen to remain without sexual partners or have tried to forge heterosexual partnerships in an effort to resist their homosexual orientation and desires. Even though same-sex sexual relations have stopped, and heterosexual sexual relations begun, such “ex-gay” clients report still thinking of themselves as gay and desiring same-sex relations; they simply do not allow themselves to have them.

Most scholars have arrived at the consensus that although some homosexual or bisexual persons may be able to resist engaging in sex with same-sex partners, the alteration or transformation of homosexuality into heterosexuality is an extremely unlikely (and

probably unhealthy) event and that an individual's sexual orientation is a relatively stable characteristic.

### What About Homosexuals Who Want to Be Heterosexual?

Most mental health professionals accept the idea that it is the very rare individual who does not undergo some discomfort and period of adjustment upon the realization of being homosexual. Because values and models set heterosexuality as the norm in our society, and because these expectations are internalized, it is consequently difficult for persons finding themselves falling outside the norm to feel comfortable with possessing a nonmajority sexual orientation.

Many mainstream clinicians who encounter a gay or lesbian client who voices a desire to change his or her sexual orientation would first ensure that such a client is not simply in the midst of a typical phase of self-doubt and fear. In addition to these reactions arising from internalized homophobia, such clients may have also encountered highly critical or even hostile social reactions when sharing with others the fact they are homosexual, thereby heightening their concerns over their homosexuality. At a societal level, media messages and conversations about the erosion of gay rights, the push to make gay partnerships illegal and to deny gay partners health insurance, and reports of hate crimes (including murder) perpetrated against gay men and lesbian women would also add up to create a reasonable level of distress, anxiety, and confusion. Finally, as aforementioned, contextual and cultural variables (racial/ethnic, religious/spiritual, intrafamilial) would need to be assessed before arriving at a conclusion that the client is making an informed and healthy decision.

### Summary

Homosexuality and same-sex sexual attraction is not a mental illness, disorder, or pathology. Therefore, not only is the need for psychological treatment or counseling not supported or indicated, but self-reports from persons undergoing conversion therapies demonstrate that such treatments may bring harm to clients. No case can be built that justifies conversion therapy as judged by the ethical standards of major mental health organizations. Finally, there is no documented empirical research that demonstrates the efficacy or effectiveness of conversion therapy; in fact,

almost all evidence of successful outcomes come from anecdotal or single source reports (e.g., therapist or client impressions) without corroborating or longitudinal evidence of stable and true change of sexual orientation or a healthy adjustment to a nonsexual lifestyle or a self-imposed heterosexual partnering.

## CORRECTIONS APPLICATIONS

---

The corrections population in the United States comprises inmates in federal and state prisons, territorial prisons, local jails, Bureau of Immigration and Customs Enforcement facilities as well as military and juvenile facilities, and this population differs across a multitude of variables compared to nonincarcerated

populations. Each of these variables individually and collectively creates challenges in providing counseling services. Counseling services are likely most effective when focused on basic needs that many inmates are unable to meet for themselves. Such needs are likely to include assuring a stable living environment upon release, the means to sustain this environment through steady employment, and the elimination of the destructive patterns, such as substance abuse, that led to a destabilization in meeting these basic needs. Although challenging, working with corrections populations can be among the most rewarding kinds of work for counseling professionals.

### **Growth of Corrections Population**

The corrections population in the United States has grown annually since 1970; over 2 million people are presently incarcerated, and over 7 million are under some form of correctional supervision (probation, parole or other supervised release, or placement in community corrections programs commonly referred to as “halfway houses”). The corrections population in the United States is between 6 and 10 times greater than that of any other industrialized country in the world. Rates of incarceration for racial and ethnic minorities are particularly discouraging. For example, two thirds of all prison inmates are minorities. One in every eight Black males in their 20s is in prison or jail on any given day. Institutional populations often exceed design capacities of the physical structures and allotted staff; state prisons operate at between 1% and 14% above capacity and federal prisons operate at 34% above capacity. This growth has thinned available resources and burdened corrections professionals.

More than half of all prison and jail inmates had a history of mental illness within the last 12 months. Rates of mental illness among female inmates (state 73%; federal 61%; jail 75%) far exceeded male rates (state 55%; federal 44%; jail 63%). Mental health problems among the corrections population are largely associated with criminal history, violent offenses, and physical aggression in prison as well as homelessness and other personal instability in the year before arrest. Estimated rates of mental illness within corrections populations typically incorporate only mood, anxiety, and psychotic disorders in their analyses and exclude developmental and substance-related disorders. Often, adjustment disorders with mood or anxiety symptoms are also not reflected in these statistics, because there

is an assumed period of maladjustment inherent to incarceration. Consequently, statistics provided for the rates of mental illness within corrections populations typically underestimate actual rates, as statistics are based on a discrete set of disorders.

Growth in the U.S. incarcerated population is partly explained by decreases in numbers of patients hospitalized in mental hospitals and asylums. Although progressive movements in the 1950s and 1960s attempted to deinstitutionalize mental illness and provide for more humane treatment within the community, limited viable alternatives to mental hospitals and poorly equipped community programs contributed to increased rates of incarceration for individuals with mental illness. Quite simply, prisons have become the modern-day mental asylum.

Substance abuse is also a significant problem within the corrections population. Over 80% of all inmates were incarcerated for a drug-related offense, were under the influence of a substance at the time of their offense, committed their offense to obtain money for drugs, or were abusing substances in the month prior to their arrest. These rates have also continued to grow over the last 30 years because of changes in public policy that resulted in increased resources to arrest and convict drug offenders, mandatory sentencing laws, cutbacks in parole releases, and increases in the revocation of probation or parole. Although drug treatment programs are by far the most widely offered forms of treatment in corrections settings, the percentage of inmates reporting participation in drug treatment programs dropped across the 1990s for both state and federal facilities.

### **Health-Related Issues**

Providing for the medical needs of the corrections population has been highly politicized since the 1976 landmark U.S. Supreme Court decision in *Estelle v. Gamble* (429 U.S. 97). This decision prohibited corrections professionals from passivity or indifference in their treatment of inmates' health problems. Although aggressive prevention and treatment of health problems is preferred, this task can be daunting given that the corrections population has far more medical illnesses than the average population, correctional institutions often have limited financial and medical resources to assure adequate treatment, and the typical inmate is not often health conscious. For example, the prevalence rates for communicable diseases among the corrections population far exceed those of the average

population; the proportion of inmates with HIV/AIDS is 5 times greater than in the total U.S. population, the proportion with hepatitis C is 9 to 10 times higher, and the proportion with tuberculosis is between 4 times higher (for prison inmates) and 17 times higher (for jail inmates). Hepatitis B and other sexually transmitted diseases (i.e., syphilis, gonorrhea, chlamydia) are also present among significant proportions of the corrections population. The prevalence rates for chronic diseases are also quite high, including heart and cerebrovascular disease, cancer, diabetes, and respiratory disease. Often, because of individual and socioeconomic barriers, illnesses are either first diagnosed in a corrections setting, or the first sustained treatment to which the inmate has access is within a corrections institution. These challenges coupled with an increasing geriatric population in prisons make successful treatment more intensive and costly.

### Substance Abuse Counseling

Although the rates of inmate participation in drug treatment programs have decreased, such programs remain a staple of psychological and rehabilitative services in correctional settings. Evidence suggests that participation in such treatment programs decreases both recidivism and continued drug use upon release. For example, the Federal Bureau of Prisons found that inmates who completed the Drug Abuse Program (DAP) were 73% less likely to be rearrested in the first year after release than untreated inmates. Additionally, a comparison of urinalyses showed that DAP inmates were 44% less likely to continue using substances after release than inmates who did not complete DAP. Research on state facilities has shown similar reductions in recidivism of around 50%. The most effective of these programs are those that combine treatment during incarceration with community aftercare upon release.

### Vocational and Academic Counseling

Some degree of vocational or academic development while incarcerated remains the most consistent factor predicting rates of recidivism. In other words, inmates who participate in vocational programming, a specific occupational apprenticeship, or an academic advancement program are less likely to reoffend upon release. According to Moore, one study conducted by the Florida Department of Corrections (DOC) concluded

that inmates who earned a GED were 8.7% less likely to recidivate than those inmates without a GED. Inmates who obtained a GED and improved their scores on the Test of Adult Basic Education to the ninth grade level or higher were 25% less likely to recidivate. Inmates who completed a vocational development program were 14.6% less likely to recidivate than those who did not complete any vocational programs. The impact of vocational and academic programs in reducing recidivism is not exclusive to Florida, as similar results are seen in other state and federal institutions.

Aside from the direct benefit to the inmate and his or her family for remaining free from further incarceration, there is a direct benefit to correctional institutions and their taxpayers. The reduction in recidivism rates for inmates who obtained a GED in the Florida study translated into approximately 100 inmates not returning to prison. The reduction in recidivism rates for inmates who completed a vocational program translated into approximately 169 inmates not returning to prison. The Florida DOC estimated that the amount saved by not having to reincarcerate the 100 inmates with a GED was approximately \$1.9 million; the savings for the 169 inmates who participated in vocational programs was \$3.2 million.

### Release and Reintegration

Approximately 97% of the U.S. incarcerated population will be released to the community. Release is extremely challenging for inmates as is evidenced in dramatically increased rates of suicide and accidental death by either overdose or homicide immediately upon release. Consequently, nearly all counseling with corrections populations should focus on release preparation.

---

## COUNSELING, DEFINITION OF

---

Professional counseling is a skilled activity that involves assisting others in managing and resolving psychological, emotional, behavioral, developmental, relational, vocational, and other personal challenges (chronic or acute) in order to facilitate adjustment to changing life circumstances; promote personal growth, needs attainment, and overall wellness throughout the life span; and prevent the development of more serious conditions. At its essence, professional counseling involves the formal application of theoretical and empirically supported psychological, developmental, and learning principles to facilitate desired change or growth within a larger system of ethical and professional practice standards. These principles are implemented through specifically tailored cognitive, affective, behavioral, and systemic strategies and

interventions delivered through therapeutically oriented conversations and interactions.

### Types of Professional Counseling

Originally derived from the Latin root, *consulo*, meaning to advise, deliberate, or consult, counseling can be conceptualized in a number of different ways. Professional counseling is provided within the context of individual, couples, family, and group formats. Some counselors define their work on the basis of developmental life stages (i.e., child counseling, adolescent counseling, adult counseling, and geriatric counseling). Counseling can also be distinguished temporally, whether it is intended to be very short-term crisis counseling, brief counseling, or long-term counseling. Distinct subspecialties within the profession of counseling include school counseling, career counseling, and mental health counseling. Counseling is also sometimes defined by the distinct underlying theoretical orientations upon which the professional counselor draws (e.g., solution-focused counseling, person-centered counseling, existential counseling).

### Differentiating Professional Counseling

There is a clear difference between professional counseling and lay counseling, with the former being bound by professional ethical standards and premised on sound theoretical and research-supported principles. Professional counseling is different from other helping activities such as guidance and health or psychoeducation in that these other activities are primarily directed at providing information and advice in an emotionally neutral context. In relation to other mental health professions, professional counseling is best distinguished by an emphasis on normal development, adaptation to changing life circumstances, and positive growth.

Although the terms *counseling* and *psychotherapy* are often used interchangeably, the two are distinct. A simple perspective may conceptualize counseling and psychotherapy as falling on a continuum, with counseling designed for normal populations and psychotherapy designed for clinical populations. To state this another way, some individuals see counseling as more concerned with adjustment to mainstream life transitions and normative stressors, while psychotherapy is seen as more concerned with psychological disorders and psychopathology. An alternative

conceptualization is to attend to the traditional paradigmatic differences between the two. Counseling typically follows a growth-oriented, developmental, and preventive framework. In contrast, psychotherapy typically adopts a medical (i.e., diagnose-and-treat) model. Although the practice of counseling is not intended specifically to diagnose and treat psychiatrically classified mental disorders in the tradition as the medical model, it is intended to facilitate wellness, personal growth, needs attainment, and adaptation to changing life circumstances. Consequently, when professional counseling is employed with individuals who meet the criteria for specific disorders, the emphasis remains on the person's ongoing adaptation, personal growth, wellness, and needs attainment. Through facilitating positive movement and change in these areas, the person's diagnosable condition may improve.

broad field of psychology, and though much of the history of each is unique, counseling and psychology are branches of the same mental health tree. The counseling field developed from the guidance movement in response to recognition of a need for mental health and guidance counseling for individuals facing developmental milestones. This entry provides a historical context for the development of the counseling profession, the key contributors to the profession, and the development of organizations providing professional context and accountability. An overview focuses on three threads: societal changes that influenced the profession in response to human need, changes in psychological theory, and educational reform.

### Early 20th Century

The counseling profession developed in many ways from responses to changes in society. In the early 20th century, when counseling was first emerging, humanistic reform, with an increased emphasis on the value of all human beings, was also emerging. Human qualities such as choice, creativity, self-realization, and ultimately the value of all people became the focus of human change and intervention. During this period of humanistic reform, society saw changes in conditions of prisons, asylums, and factories based on the humanistic principles noted above. The focus was toward treating all clients, regardless of circumstance, in a way that regarded and supported their potential for success and remediation. Concurrently, the school system was taking a lead in this transformation through its focus on humanistic education, including student-centered learning with the teacher as a facilitator, development of the self-actualized student, and student cooperation. Humanistic reform led to a new way of viewing the individual and the facilitation of human well-being.

Also during this time, America was in the midst of the Industrial Revolution, a time of great change resulting in a shift in human need. One of the primary consequences of the dramatic changes occurring in American society was the movement from farms to the city. As a great influx of people moved to cities to work in industry and in the factories, people were severely overcrowded, which ultimately resulted in an increase in disease and the beginning of slums and poverty. An additional consequence was the disorganization of the family. Before the industrial revolution, families lived close to one another, worked together, and relied on one another for support. Once families

---

## COUNSELING, HISTORY OF

---

The counseling field, though relatively new, has a rich history. It is important to note the influence of the

moved to the cities to work in the factories, the family structure changed, and the human population became increasingly isolated. These changes created new needs for the individual and the family.

In education, this time period saw the ongoing development of progressive education led by John Dewey. The focus of this movement was child learning through real-world experience and an emphasis on schools reflecting the overall life of society. Also part of this movement was respect for the child and the implementation of a curriculum that allowed for children to develop personal interests; this curriculum included agricultural education, industrial education, and social education with an emphasis on the acculturation of immigrants. Progressive education coupled with the humanistic movement shed light on the growing need to attend to the overall well-being of children, beyond the walls of the school. Another key figure in the change of American schools was Horace Mann, who is often referred to as the father of American education. Mann believed in the development of a system of common schools: universal, free, and nonsectarian education.

These early forerunners (Dewey and Mann) were focused on training and advice, in particular education and vocational guidance, and on interpersonal relationships. To this point in history, the helping professions were dominated by mental health giants such as Sigmund Freud, Alfred Adler, and Viktor Frankl. Freud's psychoanalytic theory had, and continues to have, a profound impact on counseling and psychotherapy.

The early 1900s saw the beginning of political support for compulsory education. Compulsory education allowed for education for all and is based on the fundamental principle that education is a basic human right. Specifically, compulsory education requires by law that children receive education and that government provide education to all. Educating children decreased the number of children in the labor force and was a primary force in the change of society.

During this time in France, Alfred Binet was part of a commission concerned with retardation in school children. Binet rejected some original tenets of intelligence testing and worked on the development of intelligence scales. With the changes in the educational system driven by education reform in a response to urbanization and industrialization, schools needed assistance to handle diverse learning capabilities. Binet developed a scale to differentiate children

struggling to learn from those more capable of school demands. Binet collaborated with Theodore Simon, a physician, and together they developed a measure of intelligence. The primary intent of this 1905 intelligence scale was to discriminate between slightly "retarded" children and the normal school population.

Three key figures influenced the early roots of the counseling profession, specifically Jesse B. Davis, Frank Parsons, and Clifford Beers. A front-runner in the response to educational reform, Jesse B. Davis, was the first person to develop public school counseling and guidance programs. As a principal, Davis required his students to write about their vocational interests on a weekly basis. Davis believed that character development was central to preventing behavioral problems and to creating good relationships with other students. Davis was strongly influenced by Mann and Dewey and believed that if children were given proper guidance, the challenges of an increasingly industrialized society could be met. Therefore he advocated for the infusion of vocational development into traditional curriculum. The goals of the vocational focus were to assist students in understanding their character and in becoming socially responsible workers.

Parsons, often called the father of guidance, founded Boston's Vocational Bureau in 1908. Parsons believed the more people understood themselves and the career choices available to them—specifically their aptitudes, interests, and resources, the more capable they were of making informed and reasonable occupational choices. In 1909 Parsons wrote *Choosing a Vocation*, a highly influential book that called for the designation of school teachers as vocational counselors. Other schools took Parsons's example and began implementing their own vocational guidance programs.

During this same time Beers, author of *A Mind That Found Itself* in 1908, was the impetus for the mental health movement. This book was an autobiographical account of his experience with institutionalization following a suicide attempt. After discovering the condition of these facilities and finding the treatment of mental illness ineffective, Beers committed himself to changing the treatment of the mentally ill. In this book, he exposed the conditions of mental health facilities and eventually prompted national reform in the treatment of persons with mental illness. His work was the forerunner of mental health counseling.

The above professional forces were working toward the development of the counseling profession.

Early changes across three professional movements—guidance counseling and educational reform, mental health reform, and the psychometrics movement—came together to create the foundation of the counseling profession.

As the 1900s progressed, several events occurred that impacted the profession. The first event was the founding of the National Vocational Guidance Association (NVGA) in 1913. In 1915, the NVGA published the first *National Vocational Guidance Bulletin*, and by 1921 it was publishing it regularly. In 1924, the title was changed to the *National Vocational Guidance Magazine*. The publication evolved over the years to eventually become the *Journal of Counseling and Development*, the publication's current title. The development of the NCGA signified the first effort toward unifying those invested in the pursuit of scholarly information related to vocational guidance. Also during this time, the Smith Hughes Act of 1917 was passed by Congress. This act provided funding for public schools to provide vocational guidance programs and allowed schools to separate their vocational guidance programs from standard curriculum courses.

The beginning of World War I brought many new challenges to the United States and other countries involved in the war. The U.S. Army, in response to one of their challenges, commissioned the development of the Army Alpha and Army Beta intelligence tests. During this time, counseling became increasingly recognized as the army implemented these instruments to assist in selection, placement, and training practices for army personnel. After the war ended, these instruments were used with the civilian population; this marked the beginning of the psychometrics movement, one of the professional origins on which the counseling field was largely based.

### The 1920s

The 1920s saw the emergence of an even greater influence of school guidance. During this time, the profession was becoming increasingly focused, and vocational guidance became the primary focus of training programs, starting with Harvard University. The major influences on the profession at this time were theories of education and governmental support of guidance service for war veterans. Recognition of the importance of vocational assessment and guidance continued to pull the counseling field into more solid development and recognition of the need for increased

professionalism. In response to this pull came the development of the first standards for occupational inventories and guidelines for their development and evaluation, providing further impetus for psychometric evaluation. The primary orientation during this time was the medical model and testing.

With the standards for development and evaluation of psychological instruments came an increase in the publication of these materials, most notably the Strong Vocational Interest Blank (SVIB), created and published by Edward Strong in 1927 (now called the Strong Interest Inventory). The Strong Vocational Interest Blank was developed based on the assumption that patterns of individual interests indicate likely occupational choices. The inventory indicated the occupations in which a person will be more likely to be satisfied and perhaps even continue with long-term employment.

### The 1930s

The Great Depression in the 1930s had a profound influence on both researchers and practitioners; specifically there was an increased need for helping processes and counseling for employment placement. During this time period, E. G. Williamson developed the trait-factor theory based on modifications of Parson's theory. Williamson's theory was direct and focused on the counselor's direction, primarily through teaching and mentoring. The focus of trait-factor counseling was to define behavior by traits such as aptitudes, achievements, personalities, and interest, and based on these and a variety of factors, statistically evaluate them to assist an individual toward becoming an effective and successful individual. Williamson's theory was most popular in the 1930s and 1940s when it was used by the military in World War II for selection.

In addition to the influence of the economic climate, the greatest influence on the counseling profession during this time may have been the government's interest in supporting guidance and counseling efforts. In 1936, the George-Deen Act was approved by Congress; this act allowed for the creation of the Vocational Education Division of the U.S. Office of Education. An extension of this act was the introduction of the position of state supervisor of guidance in state departments of education. The George-Deen Act represented the first time funds were directly allocated for vocational guidance counseling, and guidance counselors saw an increase in support for their work.

Also during this time, the U.S. government instituted the U.S. Employment Service, which published the first edition of the *Dictionary of Occupational Titles (DOT)*. The *DOT* was the first publication to define jobs of all types. The *DOT* continues to serve individuals seeking employment to this day.

Despite great strides in the counseling profession during this time, some professionals in the fields of education and psychology were criticizing the narrow focus on the guidance movement. In particular, Edward Thorndike felt that the focus of the guidance movement was too narrow.

### The 1940s

The 1940s represented another decade of increased recognition for counseling and the ongoing development and definition of the profession. One of the most significant events was World War II. During the war, the U.S. government employed counselors and psychologists to assist in selection and training of specialists for both the military and industry. The war also brought with it a necessary increase in the number of women in the workforce. With so many men fighting in the military, women were needed to fill the vacant positions. The role of women in the workplace during such an important time for the United States radically changed the traditional sex roles formerly dominating the workforce.

Another significant event for the field of counseling that occurred during the 1940s was a growing interest in psychotherapy. There was an emergence of diverse theories—Carl Rogers’s client-centered and nondirective theory in particular. Rogers grew in popularity after the publication of his book *Counseling and Psychotherapy*. He challenged Williamson’s directive way of working with clients and focused on the clients’ responsibility for their own growth. As is evident from the history to this point, the focus of counseling and guidance prior to Rogers was on testing, assessment, and vocations. Through Rogers’s influence, the focus of counseling shifted to relationship dynamics, counseling technique, training of counselors, and refinement of the goals of the counseling relationship. Rogers’s theory came to the forefront of counseling and psychology theories, but new counseling theories emerged as well.

Following the war, several events occurred that further promoted the counseling profession. The George Barden Act of 1946 was passed, which

allocated vocational education funds for counselor training programs: This included funding for counselor educators, research, state program supervision, local guidance supervisors, and school counselors. Also during this time, the U.S. Department of Veterans Affairs (VA) gave grants for counselors and psychologists and paid for internships for graduate students. With the combination of the George Barden Act and support from the VA, graduate training programs began defining their curriculum more clearly.

### The 1950s

Building on the major changes that occurred during the 1940s, the 1950s saw great changes and the professionalization of counseling. As mentioned previously, the counseling profession developed in the context of historical events. The 1950s were a time of great change with such historical events as the launch of Sputnik, the baby boom, the women’s rights movement, and the civil rights movement. While these events were drastically changing the country, additional simultaneous events were occurring that changed the counseling profession. Specifically, these events were the passing of the National Defense Education Act (NDEA), professional developments, the introduction of new guidance and counseling theories, and the emergence of diverse marriage and family counseling theories.

The National Defense Education Act (NDEA) was initiated in response to Sputnik, a space satellite launched by the Soviet Union. The purpose of the NDEA was to promote studies in math, science, and foreign languages. The NDEA sought to identify children with particular abilities in these academic areas. Although this was the original intent of NDEA, this act also provided funding for improving school counseling programs and for training counselors. This decade saw the greatest increase in the number of school counselors in a decade.

Concurrent to the growing numbers of counselors nationwide, the profession itself was growing and changing. 1952 saw (1) the establishment of the American Personnel and Guidance Association (APGA), (2) the establishment of Division 17, the Division of Counseling Psychology of the American Psychological Association, and (3) the founding of the American School Counselor Association (ASCA). A year after ASCA was founded, it became a division of the APGA.

Finally, the 1950s saw the emergence of many different theories. Prior to this time there were essentially four primary theoretical orientations: psychoanalysis, trait-factor theories, client-centered theories, and behavioral theories. Within these four primary orientations, practitioners worked with either nondirective or directive counseling, but during this time, new theories emerged, including cognitive theories, behavioral theories, learning theories, and career theories. Also, marriage and family therapy emerged to an even greater extent, and major theorists in the marriage and family therapy field, such as Gregory Bateson, Virginia Satir, Jay Haley, Murray Bowen, Carl Whitaker, and Salvador Minuchin were solidifying the marriage and family movement.

### The 1960s

In the 1960s, the baby boomers were growing up, and the conservatism of the 1950s was changing to reflect a new way of thinking, thus radically changing American culture. The civil rights movement saw sit-ins, protests, and assassinations. During this time, women were entering the workforce in greater numbers, and the National Organization of Women was exposing the “glass ceiling.” Also during this time, crime and drug use were increasing, and the United States was once again at war, this time in Vietnam. The societal changes of the times contributed to many changes in the counseling profession, in particular a solidification of the profession and a focus on the needs created by the societal changes during this time.

In 1963, the Community Mental Health Act was enacted. This act provided federal funding for community mental health centers and was pivotal in changing the dissemination of services for the mentally ill. It allowed for individuals who would formerly have been institutionalized to live in the community and receive mental health support and services. The Community Mental Health Act also provided funding for building new community mental health centers through the National Institute of Mental Health, thus providing additional support for the provision of community-based care. In addition to major developments in the care for the mentally ill, this act provided employment opportunities for counselors.

This decade also saw increased professionalism in the field of counseling. Specifically, the APGA published its first code of ethics, providing guidelines for ethical practice and ultimately protecting the public

and increasing professionalism. Also during this time, an APGA report was edited that defined the role of and the training standards for school counselors. The American Psychological Association, Division 17, continued to clarify the definition of the counseling psychologist and published its first professional journal, *The Counseling Psychologist*.

Another influence of the government on the development of the counseling profession was the 1966 establishment of the Education Resources Information Clearinghouse (ERIC). Specifically related to the counseling profession was the ERIC section on Counseling and Personnel Services (ERIC/CAPS) at the University of Michigan. The ERIC was funded by the Office of Educational Research and Improvement through the U.S. Department of Education. The ERIC/CAPS provided a comprehensive resource on counseling activities and trends in the United States and internationally. In addition to the development of the database, conferences on counseling were sponsored, bringing together leaders in the profession.

In 1962, Gilbert Wrenn wrote a seminal piece that further defined the role of the school counselor. Specifically, Wrenn wrote that the school counselor should fill four functions: counsel students; consult with parents, teachers, and administrators; study the changing student population and interpret this information for administrators and teachers; and coordinate counseling services in the school and between the school and the community.

As the profession grew and training standards became more rigorous, the provision and regulation of quality services also increased. This decade saw considerable growth in the group movement and a shift toward small group interaction and interpersonal growth and awareness. Other major influences on the profession during this time were the emergence of Maslow’s humanistic counseling theory and of behavioral counseling, which emphasized learning as the root of change.

The counseling profession was paralleling the societal changes of the times. Specifically, counselors were being employed in more diverse settings, such as mental health centers and community agencies. Counselor training programs were also increasing in number, meaning that more counselors were competing for jobs as the programs graduated students. Along with the increased availability of training and more diverse employment opportunities, counselors were seeking and receiving specialized training. The

term *community counselor* began to be used, paralleling the diversification of employment opportunities, with the new title implying a professional with diverse roles and responsibilities.

A pivotal movement in the counseling profession during this decade was for state and national licensure. Restrictions on counselors' ability to acquire psychology licensure led to this movement. The APGA started a task force to address licensure for counselors, and a benchmark for its success was the passing of successful licensure legislation in Virginia in 1976. Two additional states, Alabama and Arkansas, also had licensure legislation by the end of the decade.

### The 1970s

In the 1970s the profession became increasingly strong. Headquarters for the APGA were established in Alexandria, Virginia, and several strong divisions were chartered, including the Association of Counselor Education and Supervision (ACES), the American Mental Health Counseling Association (AMHCA), the Association for Religious and Value Issues in Counseling (now ASERVIC), the Association for Specialists in Group Work (ASGW), the Association for Non-White Concerns in Personnel and Guidance (ANWC), and the Public Offender Counselor Association. During this time, ACES published its first standards for master's degree programs in counseling, and it approved guidelines for doctoral education in counseling. As the profession became stronger, the APGA began questioning professional identity, as the personnel and guidance focus seemed increasingly outdated and narrow.

### The 1980s

The 1980s saw divorce rates increasing, violent crime increasing, and prisons overflowing. Drug use was considered an epidemic with the emergence of crack cocaine, and acquired immunodeficiency syndrome (AIDS) was claiming lives and demanding attention. The counseling profession continued to grow and to become a distinct profession, ultimately changing in response to divergent societal needs.

In 1981, the Council for Accreditation of Counseling and Related Education Programs (CACREP) was formed. CACREP revised the original standards developed by ACES in the 1970s. With those standards,

they standardized counselor training (counselor education) programs for both master's and doctoral students in the areas of school, community, mental health, marriage and family counseling, and personnel services.

At the same time, the National Board for Certified Counselors (NBCC) was formed in 1983. The initial intent of the NBCC was to certify counselors on a national level. A large part of this process included developing a standardized test covering eight major subject areas: (1) human growth and development, (2) social and cultural foundations, (3) helping relationships, (4) groups, (5) lifestyle and career development, (6) appraisal, (7) research and evaluation, and (8) professional orientation. Passing the exam, meeting experiential and educational requirements, and character references allowed a person to earn the National Certified Counselor (NCC) credential. Accreditation and certification standards attracted many to the profession.

A conversation continued from the late 1970s became more prevalent during the 1980s, as leaders in the APGA recognized that "personnel and guidance" no longer fit in describing the work of the members. In response, the APGA was changed to the American Association for Counseling and Development (AACD). Professional identity and commitment was increasingly important to members of AACD. Representative of this commitment was the formation of Chi Sigma Iota, the academic and professional honors society for counselors. Chi Sigma Iota was formed by Thomas J. Sweeney to promote excellence in the counseling profession.

AACD saw an increase in membership and an increase in the number of divisions, highlighting the diversification in the counseling field. Throughout this decade, the focus on developmental issues across the life span was led by developmental theorists such as Erik Erikson and Lawrence Kohlberg. A new division of the AACD, the Association for Multicultural Counseling and Development (AMCD) represented an increased focus on recognizing the challenges of counseling individuals from diverse ethnic and cultural backgrounds.

### The 1990s

The technology boom, low unemployment rates, and highly publicized violence (the Los Angeles riots, the World Trade Center bombing, the O. J. Simpson trial,

the Oklahoma City bombing, and school shootings) marked the 1990s. During this time the counseling profession was continuing to define itself professionally, was demanding appropriate supervision in response to the diverse needs of counseling consumers, and was dealing with restricted funding. Two primary influences in the 1990s, in addition to advances in technology, were managed care and an increase in accountability.

In 1992, the AACD instituted another name change, this time to the American Counseling Association (ACA). Also in 1992, counseling was included in the healthcare human resource statistics compiled by the Center for Mental Health Services and the National Institute of Mental Health, marking counseling as a primary mental health profession. A final key event that occurred in 1992 was the writing of multicultural counseling standards and competencies by Derald Wing Sue, Patricia Arredondo, and Roderick McDavis.

Finally, during this time there was a return to emphasizing counseling the whole person; this meant counselors took into consideration the importance of societal influences and the context of a client's life, such as his or her spirituality, family, and occupation. Organizations established in the 1970s and 1980s such as CACREP, Chi Sigma Iota, and NBCC experienced continued growth during this time, more states were passing licensure legislation for counselors, and both ACA and APA were publishing articles and books on counseling.

## COUNSELING PSYCHOLOGY, DEFINITION OF

---

Division 17 of the American Psychological Association (APA), known today as the Society of Counseling Psychology, has endured several challenges in formulating and refining a description of what defines it as a specialty. Prior to the creation of Division 17, the core of counseling as a profession had primarily been in vocational guidance. In 1946, Division 17 of the APA, titled the Division of Counseling and Guidance, was created. Although counseling psychology became a separate division at this time, the division still lacked a defining description that separated it as a unique specialty. Since Division 12 (Clinical Psychology) was already well established, the Division of Counseling and Guidance was encouraged to establish standards for training and practice in the same way that clinical psychology had. It wasn't until 1951 that the field of counseling psychology emerged as a separate specialty. It was during this year that the job title of counseling psychologist came into use.

In 1951, Division 17 sponsored the Northwestern Conference on the Standards for Training Counseling Psychologists. During this conference participants discussed defining descriptions of the roles and functions of counseling psychologists. It was also during this time that the name of Division 17 was changed to the Division of Counseling Psychology. Under this new title the description of counseling psychologists included the following:

The counseling psychologist is to foster the psychological development of the individual. This includes all people on the adjustment continuum from those who function at tolerable levels of adequacy to those suffering from more severe psychological disturbances. The counseling psychologists will spend the bulk of their time with individuals within the normal range of functioning, but their training should qualify them to work to some degree with individuals at any level of psychological adjustment. Counseling stresses the positive and preventative. It focuses upon the stimulation of personal development to maximize personal and social effectiveness and to forestall psychologically crippling disabilities.

Within this new definition, counseling psychologists extended their role beyond the primary confines of vocational guidance and attempted to help people with all types of life adjustments. However, there continued to be conflicts regarding the status and proper focus of this new specialty. Another conference held in Atlanta in 1987 provided increased clarity on the focus and status of counseling psychology. At this conference the “valued characteristics” of counseling psychology were explicated. These characteristics included an emphasis on positive mental health, strengths-based adjustment and coping, empowerment of individuals, advocacy, political involvement, and direct teaching of skills. Promotion of mental health was not only encouraged at the individual level but extended to groups and systems. Counseling psychology was considered to impact development across the entire life span, to address adjustment and satisfaction in vocational as well as personal spheres, and to incorporate prevention and remediation strategies. In addition, viewing people and their behavior within a sociocultural context influenced by variables of culture, ethnicity, gender, sexual orientation, age, and sociohistorical perspectives was also considered of paramount importance.

In 1999, the APA published the *Archival Description of Counseling Psychology* that recognized and affirmed counseling psychology as an applied specialty. The current definition and parameters of the profession are described as follows:

Counseling Psychology is a general practice and health service–provider specialty in professional psychology. It focuses on personal and interpersonal functioning across the life span and on emotional, social, vocational, educational, health-related, developmental, and organizational concerns. Counseling psychology centers on typical or normal development issues as well as atypical or disordered development as it applies to human experience from individual, family, group, systems, and organizational perspectives. Counseling psychologists help people with physical, emotional, and mental disorders improve well-being, alleviate distress and maladjustment, and resolve crises. In addition, practitioners in this professional specialty provide assessment, diagnosis, and treatment of psychopathology. Within the context of life-span development, counseling psychologists focus on healthy aspects and strengths of the client (individual, couple, family, group, system, or organization), environmental/situation influences (including the context of cultural, gender, and lifestyle issues), and the role of career and vocation on individual development and functioning. (p. 589)

## COUNSELING PSYCHOLOGY, HISTORY OF

---

Counseling psychology emerged as an applied specialty within the American Psychological Association (APA) in the 1940s. It has been recognized as a specialty by the APA since 1946, and this recognition was reaffirmed in 1998 when the APA initiated a new period of application for specialty recognition. Landmarks in the history of counseling psychology include the establishment of the discipline in relation to the overall profession of psychology, the creation of key professional journals, and important conferences held across the years. Two organizations are considered key in the formation and development of counseling psychology: the Society of Counseling Psychology (SCP) of the APA and the Council of Counseling Psychology Training Programs (CCPTP),

the organization for directors of training programs in counseling psychology. Prior to 2004, SCP was typically referred to as “Division 17,” so reviewers of original historical material should note this reference. In the present entry, the terms *SCP* and *Division 17* will be used as seems historically appropriate.

John Whiteley, a noted historian of counseling psychology, identifies the most distant seeds of counseling psychology in the vocational guidance, mental hygiene, and psychometrics/individual differences movements along with the emergence of nonmedical and nonpsychoanalytic forms of counseling interventions such as Carl Rogers’s person-centered therapy. Later, the growth of counseling psychology was spurred by the demand for psychological services created by the veterans returning from World War II. Negotiations among representatives from the APA’s divisions 12 (Clinical Psychology) and 17 (then called Counseling and Guidance) and what was then the Veterans Administration’s Central Office Staff in Clinical Psychology resulted in the creation of a new position for psychologists in the VA system, “Counseling Psychologist (Vocational)” in 1952 to aid veterans in their readjustment to civilian life. Because helping veterans gain employment and education opportunities required different knowledge and skills than addressing psychopathology and neurological injuries, this new position helped counseling psychology to differentiate from psychiatry and clinical psychology and resulted in the growth of the vocational guidance movement.

In 1946, APA recognized Division 17, Counseling and Guidance. Counseling psychology topics began to be regularly reviewed in the *Annual Review of Psychology* under this title. The *Annual Review of Psychology* helped to further legitimize the specialty by creating a place for routine evaluation of the literature. In the 1950s, the explosion of enrollment in higher education and the needs of the returning World War II veterans spurred significant research in the areas of career development and counseling orientations. Theories of human development and behavior grew out of these economic and social forces during this time period, and client-centered, directive, learning, psychodynamic, humanistic, and existential theories further developed.

Counseling psychologists held the first major conference on counseling psychology, the Northwestern conference, in 1951. T. C. Gilbert Wrenn, the president of Division 17 at the time of the conference, addressed

the circumstances that he considered critical leading up to the conference, focusing mainly on the content of training for doctoral-level counseling psychologists, including practicum training. The Northwestern conference resulted in the first set of standards for doctoral training in counseling psychology and the formation of the Division 17 Committee on Definition. In 1956, the committee's report, *Counseling Psychology as a Specialty*, was an attempt to create a more inclusive statement defining counseling psychology. Donald Super, the next president of Division 17 after Wrenn, expanded on the statements made at the Northwestern conference. He helped to clarify the functions of the division by assigning the Committee on Definition the task of developing a formal statement regarding the boundaries and focus of the specialty and discussing the need to differentiate between counseling and clinical psychology.

In 1952 the official name of Division 17 was changed to Counseling Psychology, and the American Board of Examiners in Professional Psychology announced that its diplomas would include the term *Counseling Psychology* rather than *Counseling and Guidance*. The appearance of the *Journal of Counseling Psychology* in 1954 and the continued reviews in *Annual Review of Psychology* helped further establish the professional identity of counseling psychology.

### A Crisis of Identity

Following this period of scientific and theoretical developments, disagreement emerged within the specialty regarding the role and definition of counseling psychology. Milton E. Hahn's Division 17 presidential address in 1954 highlighted the differing conceptions of the developing profession by attempting to differentiate clinical psychology from counseling psychology. He argued that although training in clinical and counseling doctoral programs were similar, there was evidence that students were not being trained to assume the same professional roles and functions. Emphasizing counseling psychology's concerns with less severely disturbed individuals (and pointing out that they worked with *clients*, not *patients*), Hahn saw counseling psychologists as more interested in research and administration than were clinical psychologists. Clinical psychologists were likely to work in medically related modes and settings and were more oriented toward personality reorganization.

Counseling psychologists were trained to help clients to change attitudes and value systems and to address vocational concerns. In Hahn's view, they were taught to stress psychological strengths and health rather than psychopathology, diagnosis, and remedial psychotherapies.

The crisis of identity, however, did not resolve, and in 1959, the APA Education and Training Board commissioned four appraisals regarding the status of counseling psychology. The reports were so divergent that one of the four was suppressed and the other three remained unpublished for 20 years. The most negative of these reports argued that counseling psychology was on the decline and that its scientific basis was inadequate. Leaders of the specialty responded quickly, and Leona Tyler, David Tiedeman, and C. Gilbert Wrenn formulated a response refuting the gloom and doom orientation of the original reports. Their statement documented the historical grounding of the specialty (e.g., official statements on definition and on education and training), studies of the roles and functions of counseling psychologists, and social demands for counseling psychologists. It was approved by the 1960–1961 and 1961–1962 Executive Committees of the Division of Counseling Psychology.

### A Pivotal Conference

One of the most important events in the history of counseling psychology was the Greyston conference in 1964. Before the conference, counseling psychology was at a crossroads regarding identity issues and the future direction of the specialty. The purpose of the Greyston conference was to examine the professional preparation and work of counseling psychologists and to develop specific recommendations in these areas. Six formal papers provided a starting point for the conference, documenting the history of the specialty and discussing identity issues. A formal conference report was issued that presented a comprehensive picture of the profession through a review of the positions counseling psychologists held, a review of the settings in which they worked, and a summary of the important statements and official documents of Division 17.

### The First Formal Definition

Previously, statements on the definition of the specialty of counseling psychology had been circulated mostly within the membership of Division 17. The first

comprehensive, widely circulated statement regarding the definition of the specialty was published by the Teacher's College Press and copyrighted by the APA in 1968. The definition began as a project of the Professional Affairs Committee of Division 17 and was officially sanctioned by the division's Executive Committee. The definition stipulated that counseling psychologists perform administrative tasks, professional practice, and research. Three different roles were described for counseling psychologists: remedial or rehabilitative, preventive, and educative and developmental. The definition also included information about counseling psychologists' jobs and work settings.

### A Second Journal Established

*The Counseling Psychologist* was founded in 1969. Proposed by founding editor John M. Whiteley, *The Counseling Psychologist* is the official publication of the SCP. Issues are organized around specific topics and contain a major contribution accompanied by invited critical analyses from prominent scholars or practitioners. The authors of the major contribution are then invited to respond to the analyses. The issues of *The Counseling Psychologist* are based on substantive research; they have focused on human development, counseling theory, counseling methods, and professional issues. Early major contribution topics were vocational development theory, client-centered therapy, student unrest, and behavior counseling. Recent issues of *The Counseling Psychologist* include major contributions titled Social Justice and Multicultural Competence in Counseling Psychology, A Work-Oriented Midcareer Development Model, Evidence-Based Scientist-Practitioner Training, and the Internationalization of Counseling Psychology. Historically, *The Counseling Psychologist* has functioned as a repository for historical material and debates about professional identity; more recently, it also publishes the minutes of the SCP Executive Board meetings and the yearly presidential address.

### The 1960s and Early 1970s

Changes in social attitudes born in the 1960s and early 1970s affected counseling psychology in a variety of ways. These new social attitudes had sprung from a number of sources: (1) the Vietnam War, (2) emerging conceptions of self and the actualization thereof prevalent in the 1970s, and (3) challenges of traditional

attitudes and authority and the disruption of the Watergate era. Significant changes in society brought concern for equality and calls for equal rights for racial and ethnic minorities, women, and the physically challenged. Counseling psychologists responded by emphasizing psychoeducation and prevention as the 1960s trend for the search of the ideal self and personal fulfillment prevailed. The roots of counseling psychology's expertise in issues of cultural and individual diversity strengthened during this time.

Cultural themes promoting personal fulfillment and the exploration of personal relationships also created an increased demand for services that counseling psychologists provided. Consequently, counseling psychologists were found engaged with diverse clients in a wide variety of employment settings. Behavior therapy and existential approaches to counseling were two of the major theoretical issues being debated during this period, and there was continued elaboration of research on theories of career, occupational, vocational, and personality development as well as psychotherapy and counseling.

### Further Initiatives in Identity

The late 1970s and early 1980s were characterized by further examinations of the professional identity of the specialty. Whiteley identified four initiatives of organized counseling psychology in this time period. The first initiative was set in motion by Bruce Fretz, who organized views of professional identity from (1) individuals who primarily identified as counseling psychologists, (2) professionals who worked closely with counseling psychologists, and (3) two previous presidents of SCP. In 1977, these views were published in *The Counseling Psychologist*. The second initiative was led by Whiteley to project what adaptations would be needed in order for counseling psychology to have an important role into the 21st century, resulting in a book by Whiteley and Fretz and an issue of *The Counseling Psychologist* on the future of counseling psychology. The third project, organized by the APA, was to further define the specialties within psychology by issuing statements on the significant characteristics, certification, and licensing of counseling psychologists.

The fourth initiative was the Next Decade Project of Division 17, initiated by the Division 17 Executive Board and led by Norman Kagan. Similar to the second initiative, the Next Decade Project defined

challenges and the needed direction for professional practice, education and training, definitional concerns, and scientific affairs. The project was intended to strengthen the future of the profession through providing (1) a long-range guide for the division's major standing committees, (2) statements regarding licensing, and (3) documents to describe counseling psychology to future students and other professions and specialties within and outside of the profession of psychology. The findings of the Next Decade Project were published in *The Counseling Psychologist* in 1982.

Reviews of counseling psychology research published in the *Annual Review of Psychology* between 1978 and 1984 were titled Career Development, Counseling Psychology, and Career Interventions. In 1983, the publication of the first handbooks, the *Handbook on Counseling Psychology* and the *Handbook of Vocational Psychology*, further underscored the solidifying professional identity of counseling psychology. Studies of psychometrics, college student development, career and vocational psychology, and counseling process and interventions continued to enhance the profession through the theoretical and research literature. Between 1977 and 1983, 5 new volumes of *The Counseling Psychologist* and the first 10 books in the Book Series in Counseling Psychology focused on theoretical approaches to counseling, counseling supervision, and professional roles and settings. Two issues of *The Counseling Psychologist* separately addressed counseling men and women, a harbinger of the diversity movement to come.

### Emphasis on Diversity

In the late 1980s and 1990s, issues of cultural and individual diversity, long integral to counseling psychology, rose in prominence more broadly in the profession of psychology and in society at large. The origins of the specialty in career and vocational psychology prompted counseling psychologists to attend closely to individual differences, and the orientation toward strengths further supported this focus. Over the years since the emergence of the specialty, counseling psychologists have produced significant scholarship on diversity issues and have been leaders in this area within organized psychology. In 1970 the APA directed attention to the issues faced by women when it created the Task Force on the Status of Women. This task force was charged with the objective of creating recommendations about the treatment of women in

the profession of psychology and included a significant number of counseling psychologists. Division 35: The Psychology of Women was recognized by APA a short time later, in 1973, with many counseling psychologists as members then and now.

In the 1980s, issues based on race and ethnicity along with gender and sexual orientation became a focus for Division 17. To address these issues Division 17 focused on three main initiatives. These initiatives addressed increasing diversity (1) in the governing body of Division 17, (2) among the students in counseling psychology programs, and (3) in the theoretical and methodological structures of counseling psychology.

In 2002 the APA Council of Representatives adopted a set of guidelines about how psychologists should approach multicultural education, training, research, practice, and organization. Crafted as a joint effort between Division 17 and Division 45 (the Society for the Psychological Study of Ethnic Minority Issues), these guidelines originated in a writing group chaired by counseling psychologists Nadya Fouad and Patricia Arredondo; the group also included Allen Ivey and Michael D'Andrea. The guidelines attempted to fulfill four primary goals: (1) to explain the necessity for cultural awareness within psychology as a profession, (2) to present research to support the recommendations, (3) to define directions for further education in cultural awareness, and (4) to introduce perspectives that would broaden the focus of the profession of psychology. Other guidelines for diverse groups have been promulgated across the years as well; these have dealt with gay, lesbian, and bisexual clients and with older adult clients. The *Guidelines for Psychological Practice With Girls and Women* have recently been adopted. Counseling psychologists have been involved in all of these efforts.

Organizationally, counseling psychology has attended to issues of diversity by establishing within the SCP an APA Council of Representatives seat to be filled by a minority individual. Sections and interest groups of the SCP have formed around racial and ethnic diversity; advancement for women; lesbian, gay, and bisexual awareness; older adults; and men and masculinity.

### Independent Practice

As the 1980s moved into the 1990s, an increasing number of graduates from counseling psychology programs were moving into independent practice resulting in several new problems that the field of

counseling psychology had to address. Prior to the 1970s, psychologists mainly were paid directly by the government or by the people that came to see them. However, the advent of mental health coverage within health insurance policies brought an increase in third-party payers in the 1980s and 1990s. The Section on Independent Practice was created in 1996 in an effort to address these issues within Division 17. In addition, counseling psychologists began to recognize a need for the specialty to have a voice when professional and legal issues related to practice were debated. With increasing monitoring of the healthcare profession in the 1990s and new laws and policies being drafted that would have an impact on how counseling psychologists functioned within the healthcare system, it was increasingly important for Division 17 to be involved. In 1995 the SCP created the position of federal advocacy coordinator with Sandy Shullman as the first person to hold the position.

### Reorganizations of Division 17

In the early 1990s, the leaders of Division 17 began to realize that the structure of the division was not sufficient to support the growing needs of counseling psychology. In 1992 a retreat was held by the Executive Board, led by Punky Heppner and Jean Carter. The resulting plan was implemented over several years, ranging from 1993 through 1995.

The plan proposed that the governing structure of Division 17 should resemble that of the APA. Interest in increasing participation in the division prompted the implementation of a new structure for groups of members that shared common interests. This new structure included sections—groups of 50 or more members with a common interest, and special interest groups for 10 to 49 members. Special task groups could be created by the president for the accomplishment of specific objectives. In addition to the standard positions of president, secretary, and treasurer, one of the changes to the structure of Division 17 was to add new vice president positions for four issues: diversity and public interest, education and training, professional practice, and scientific affairs.

In 2002 Division 17 underwent another adaptation by formally changing the name of the division to the Society of Counseling Psychology. The intent of the name change was to perceptually define more organizational autonomy within the APA. In addition, the change would further differentiate the division from other divisions to students learning about the structure

of the APA. Most recently, in 2006 a proposal was made to again change the SCP bylaws, creating another new position within the leadership: vice president of communication. This new vice president will manage the transfer of information within SCP membership, to APA and other professional organizations, and to the general public.

### The Council of Counseling Psychology Training Programs

The Council of Counseling Psychology Training Programs was formed in 1975 for two purposes. The first was to represent counseling psychologists wherever issues concerning education and training of counseling psychologists arose. The second purpose was to disseminate information relevant to education and training to those involved in it. Over the years, CCPTP has monitored accreditation issues; gathered information on counseling psychology programs, faculty, and students; and established model policy and curriculum. In 1998, a joint initiative of CCPTP and Division 17 resulted in the Model Training Program in counseling psychology. The Model Training Program identifies the philosophy endorsed by those who train counseling psychologists (e.g., scientist–practitioner model, orientation toward strengths vs. pathology) and identifies content areas integral to education and training in counseling psychology (e.g., supervision, career and vocational psychology, diversity) beyond the core content of professional psychology.

### Contributions to Supervision

Starting in the late 1970s, counseling psychologists began to focus on one of the unique processes of becoming a counseling psychologist: the supervisory relationship. Although psychologists had ruminated over the issue of the supervision relationship since the beginning of psychology training, only recently has research and theory in the area really begun to develop. In 1979 J. M. Littrell, N. Lee-Borden, and J. A. Lorenz proposed a model of the supervision relationship. Models developed by Carol Loganbill, Emily Hardy, and Ursula Delworth and then by Cal Stoltenberg and Delworth followed in 1982 and 1987, respectively. These contributions sparked interest in theory and research on supervision that continues in the 2000s. Supervision is also considered a key element in the education and training of counseling psychologists and is therefore an important element in the Model Training Program.

## Integrating Science and Practice

One of the ongoing debates within Division 17 is the implementation of the scientist–practitioner model, specifically, how to balance attention to scholarship and practice with attention to theory, research, practice, and training. In the early years of Division 17, most of the governing body consisted of full-time academic psychologists. In the 1980s, and especially in the 1990s after the division’s reorganization, the presence of full-time practitioners of counseling psychology increased.

In the early 1990s, a task force was assigned the objective of developing recommendations for integrating science and practice within counseling psychology. The task force was chaired by Puncy Heppner, and its recommendations were published in 1992. The recommendations emphasized integrating science and practice in doctoral training and enhancing training in research methods for counseling psychology students.

Counseling psychologists continue to contribute significantly in understanding the integration of science and practice. Partially in response to clinical psychology’s efforts to compose a list of empirically supported treatments, counseling psychologists formulated a position on empirically supported treatments. The SCP Executive Board supported this position by forming a special task group to promote it in 2004. In 2005 a special task group was formed by APA to draft recommendations on the integration of science and practice; counseling psychology was represented by three members. Also in 2005, the APA adapted a new policy on evidence-based practice derived from the recommendations of the special task group.

Counseling psychology continues to be a major force in professional psychology in the 2000s. Members of the specialty contribute to professional psychology and to the public through research, training, practice, and service. Although counseling psychologists are found in many settings and jobs, the specialty retains its emphasis on client strengths and resources in providing preventive, educative, and remedial interventions.

## COUNSELING THE ELDERLY

---

The continued growth of the elderly population in society has placed renewed focus on providing older adults with quality mental health care. The aging of the baby boomers in combination with research indicating that psychotherapy is effective with an older population highlights the need for those with expertise in counseling the elderly.

Providing therapeutic services to an older adult population has not historically been considered an option, as age and developmental status were thought to be key determinants of psychological appropriateness. This negativistic view of counseling for the elderly appears rooted in the Freudian tradition, with the assumption that older adults were too rigid in their character structures for therapeutic change to occur. Newer theories have extended the idea of psychological mindedness into the later years of life, with counseling as a useful option for providing therapeutic support and intervention for those nearing the end of the life span.

## Universality

There are no single characteristics that accurately describe “older adults,” as this cohort encompasses an array of different life experiences, personality traits, and goals for counseling. Thus, counseling the elderly must begin with basic knowledge of the aging process,

such as normal versus pathological aging, fact versus fiction, and stereotypes. Counselors should be versed in the physical, mental, and emotional aspects of older clients and adept at clinical diagnoses specifically applicable to this population, such as differentiation between depression and dementia.

The majority of counseling approaches build upon a foundation of respect, empathy, and support. Creating a culture where mentally healthy older adults are considered “normal” is paramount to the field of geriatric counseling. Counselors must promote the idea that old age in itself is not pathological and does not necessarily require counseling. However, when symptoms increase beyond the level of the older adult’s ability to function, counseling should be an option, regardless of age.

### **Common Presenting Concerns and Psychological Disorders**

Although advanced age is not equated with psychological problems, the elderly in this society experience common areas of concern during later life. Misdiagnosis often occurs due to the belief that all older adults are depressed and that negative thoughts and feelings are normal for someone in this stage of life.

#### ***Presenting Issues***

Many older adults experience grief and loss, whether it be in their occupation (e.g., retirement), mobility (e.g., becoming reliant on a walker), independence (e.g., not being able to drive), or interpersonal relationships (e.g., death of spouse or friends). By definition, elderly clients have experienced the loss of youth and therefore all too often their own perceived value in today’s youth-focused society. Issues of loss, death and dying, physical and mental health changes, chronic illness and disability, and debilitating pain are often intertwined for the older client.

The fear of cognitive decline or “losing one’s mind” often becomes increasingly prevalent with age. Older adults are often more susceptible to delirium (a disturbance of consciousness and a change in thought process that develops over a short period of time) due to infections, medication interactions, or dehydration. Dementias (multiple deficits in thought, including impairment in memory) are varied; they may be Alzheimer’s type, vascular, or the result of other disease processes. When cognitive decline occurs,

counselors must be not only astute in detection and differentiation of cause but also aware of the client’s capacity to participate in the decision-making process—including participation in counseling.

#### ***Psychological Disorders***

As many older adults are likely to visit their primary care physician first when experiencing problems, psychological problems may be reported in somatic terms. Elderly clients may express concerns about sleep disturbance, headaches, loss of appetite, or weight change rather than identifying anxiety, feelings of hopelessness, or depression. Counselors will gain increased understanding by assessing to what extent client symptoms are due to psychological factors and to what extent they are due to biochemical disturbance.

The most common psychological disorders in the elderly population include anxiety, depression, insomnia, cognitive impairment, and adjustment disorder. If an older adult is living in an assisted living facility or nursing home, the chance of experiencing these disorders increases. Each disorder has various levels of severity. For example, depression can range from a reactive sadness (stemming from minor occurrences) to grief (a normal response to painful loss) and to clinical depression with symptoms causing impairment in daily functioning. Risk for suicidal ideation increases with depressive symptoms, and it should not be overlooked in an elderly population. Older White men are one of the fastest growing groups at risk for suicide. In general, older adults complete 20% of all suicides, although they make up only 13% of the population. In assessment for suicide risk, the counselor must be savvy in regard to identification of suicidal ideation and the possibility of taking action to cause death in contrast to verbalization of “wanting” or “being ready” to die.

In addition to the above disorders, the counselor should be aware of the possibility for substance use, including abuse of alcohol and prescription medications. Substance abuse or dependence is often overlooked within this population because of their reduced social and occupational functioning. Signs may more often present as poor self-care, unexplained falls, malnutrition, and medical illnesses.

Counselors should also be able to identify chronic mental illness and personality disorders when they occur in elderly clients. As young people with a chronic mental illness age, they become older adults with a chronic mental illness. Although the severity of

behaviors associated with personality disorders is often thought to diminish with age, the severity may increase under stress or as individuals experience a loss of control, such as a change in living situation.

## **Types of Counseling**

Counseling has been found to be effective for older adults experiencing distress, and it's clearly superior to medication because of the increased risk of pharmacological side effects in the elderly. When indicated, a combination of medication and counseling can be a successful intervention for psychological symptoms.

Both individual and group counseling are available for older adults seeking mental health treatment. Individual counseling provides older clients the time and privacy to discuss thoughts and feelings they may be experiencing. Group counseling has also been shown to be efficacious with an elderly population, and it provides an additional benefit of decreased isolation through interaction among members. Common types of groups include reminiscence (integrating past memories into present-day functioning), interpersonal (exploring personal interactions and relationships), current events (encouraging attention to current news), and adjustment (focusing on transitions).

Regardless of the type of counseling intervention, a thorough assessment of the client's needs is required. A clinical interview is often sufficient, but additional age-sensitive instruments (e.g., Geriatric Depression Inventory) can be used when further assessment is needed. In addition, counselors should be knowledgeable of when to refer (e.g., to a primary care physician to rule out medical concerns, to a specialist such as a neuropsychologist for cognitive testing, or to a nutritionist for further exploration of diet) as well as aware of appropriate community resources.

## **Adaptations to the Counseling Process**

Once an elderly client accesses mental health care, several adaptations to the traditional format allow the counseling experience to be of maximum benefit. Counselors need to be aware of the social context in which their older adult clients exist and the challenges of navigating an ageist world. For many older adults, entering into counseling is a new and possibly intimidating experience. Education about the counseling process may assist with rapport building and setting

appropriate expectations. By outlining the logistics of the sessions (e.g., how long each meeting will last, the cost, and duration of therapy) and describing the process of therapy, the counselor can potentially alleviate concerns, allowing older clients to be active participants in the course of treatment.

Counselors may allow for additional time to explain the progression of counseling, describing their theoretical orientation and therapeutic approach in a jargon-free manner, using concrete terms and examples when possible. Choice of terminology is significant, as counselors may wish to refrain from using more informal language (e.g., "that's cool" or "I get it"). Counselors should also be cautious of using terms with potential negative meaning too quickly, as older clients may not identify with being "depressed" but may instead more readily agree to "feeling blue," "being down in the dumps," or "having low spirits." Older clients may indicate anxiety by noting they are "climbing the walls" or stating something such as, "I don't feel right in my skin." Other aging clients may be more comfortable beginning the conversation about symptoms by sharing, "I just haven't felt like myself."

The development of rapport and client conceptualization is also assisted when the counselor understands the broad historical timeline of events that may have influenced an elderly person's perspective on life. A general awareness of the social impact of wars, the Great Depression, and other historical events may help clients to feel that the counselor is interested in understanding their stage in life. Although each person will experience events in a unique way, a basic understanding about major events this cohort has survived may facilitate the therapeutic process.

Older clients may exhibit physical declines that affect the course of therapy. They may have difficulty hearing, and provisions can be made to ease the frustrations of both parties to the counseling relationship. This may mean that the counselor must enunciate more clearly, speak louder, speak in a deeper voice, and possibly speak more slowly, or it may mean that the client requires assistive devices such as hearing aids or an amplification set. Because some clients may have decreased eyesight, counselors may wish to have written materials in large print. They should be prepared if older clients experience physical limitations preventing them from completing paperwork or providing a signature.

In addition, counselors may want to decrease the pace of therapy; this may be an effective method of

ensuring client understanding. Clinicians should be prepared for clients that have overall changes in memory functioning; clinicians may need to use more repetition, provide hands-on material, and focus on events and emotions that are more easily recalled. Complex and jargon-filled interpretations will likely not be successful, as many older adults may be more receptive to pragmatic and problem-solving techniques.

In addition, modifications to therapy may be necessary due to caregiving issues or living situation. As a person ceases working outside the home, becomes less able to participate in the community, or experiences family and friends passing away, the potential to become isolated intensifies. Focus is often placed on a spouse or family members, but this is accompanied by conflicting feelings, as many older adults worry about becoming a burden to their family. On occasion, caregivers might be included in the counseling process to explore such concerns.

Unique issues also arise given various living environments, as older adults who live independently in the community experience different challenges than those living with family, those with the help of a caregiver, or those living in an assisted living facility or long-term care facility. Counselors need to understand the system in which the client lives, so they can better recognize and appreciate the corresponding challenges that may arise. For instance, if a client living in a long-term care facility complains of clothes that are missing and being worn by someone else, the counselor must determine if the client is demonstrating signs of paranoia or memory deficits, describing a thief that is employed in the building, or describing a situation that the facility must address within their laundry department.

### ***Transference and Countertransference***

As both client and counselor learn more about societal perceptions of older adulthood, they must be aware of the potential dynamics that may develop. Transference involves the attribution of characteristics, traits, or behaviors to a person based on ideas about who the person is reminiscent of or who he or she represents. Thus, older clients may look at a younger therapist and reflect on their own mortality, their loss of relationships or independence, or their physical impairments. They may think it impossible that someone so much younger could understand their thoughts and feelings at the later stage in life. A younger therapist may focus too much on illness or death, or may

treat an older client as “grouchy” or “fragile,” or may think of the client as a “kind grandparent-like” individual. When appropriate, talking about the possibility for misperceptions can lead to fertile conversations about age and the counseling process.

Although it is rarely mentioned, a potential challenge of working with older clients is the increased likelihood of experiencing a client’s death. Counselors may be aware of their reaction to client death as being a double-level experience. As humans, they may face grief, guilt, and loss similar to others who have lost a close relationship. But counselors may also be cognizant of the client’s death in terms of their special role in that person’s life. This can have the potential to be confusing, emotionally draining, and isolating for counselors working with the elderly.

### **Reducing Barriers to Counseling Services**

Older adults often face multiple challenges in obtaining counseling services due to physical, financial, and cultural obstacles. Limited physical mobility and restricted access to transportation can make attending appointments difficult. For those coping with such a loss of independence, “nonessential” activities such as therapy may quickly be cut from the list of priorities. Similarly, for those on a limited financial budget, interventions that are not quickly determined to be useful may likely be discontinued. Some clients may also need assistance navigating the tricky waters of Medicare benefits. This leads to the need for therapy to be accessible, financially feasible, and most important, something that is valued by the client as helpful. In an older population that may view counseling as something for those only with severe psychological problems, overcoming the stigma of therapy can be a challenge in itself.

In addition to reducing possible barriers, counselors working with the elderly are encouraged to operate within a multidisciplinary approach, working closely with other care providers involved, such as the primary care physician, a case manager, or a concerned family member. Creating a trusting relationship with the client may be more easily facilitated if the person has confidence in the network of those providing care.

### **Conclusion**

There are endless events and experiences to recall in counseling for those who are nearing a century of life.

Older adulthood, although not synonymous with psychological health, does symbolize a certain resiliency. Helping those older adults experiencing distress to remember the strengths they have utilized throughout their lives and discussing ways to enhance these personal resources has the potential to be a rewarding experience for those counseling the elderly.

counseling is more intense and at times more complicated than work with individuals. Previously referred to as *marital counseling*, the term was limiting, as it did not include nonmarried cohabiting couples or committed same-sex couples. Subsequently the term *couple counseling* is often used to more broadly encompass any intimate, committed couple.

This entry provides an overview of the history of couple and marital counseling, approaches to couple and marital counseling, common issues in couple and marital counseling, and challenges often encountered in doing couple and marital counseling.

### Historical Underpinnings

As a distinct professional counseling service, couple and marital counseling is relatively young. Broderick and Schrader trace the history of couple and marriage counseling in four phases: the pioneer phase, the establishment phase, the consolidation phase, and the formative stage. Prior to the pioneer phase and the couple and marriage counseling movement, marital counseling was done informally by friends, other family members, or religious leaders. Also, prior to the 1930s, the theory and practice of counselors and psychologists centered on helping the individual. As families in the United States became less centralized and more geographically expansive, extended family members and other community supports were less available, and relationship counseling became increasingly necessary.

Each of the phases listed above was marked by significant events. In the pioneer phase of the early 1930s, three professional centers for marriage counseling were established: a center in Los Angeles called the American Institute of Family Relations, a center in New York, and a center in Philadelphia called The Marriage Council. From these examples, other training, research, and service centers emerged throughout the mid-1930s to mid-1940s. However, an increased need for professional unity emerged. In 1945, professionals working with couples in a counseling relationship organized to form the American Association of Marriage Counselors (AAMC). This early association included professionals from diverse backgrounds, including clergy, physicians, social workers, and family guidance professionals. These professionals were primarily responsible for some other type of work but counseled couples as part of their primary role. This signified the emergence of the establishment phase.

---

## COUPLE AND MARITAL COUNSELING

---

Couple and marital counseling helps couples, married or not, identify problems, manage difficulties, and ultimately improve their relationship. The intensity of an intimate relationship makes it one of the most important relationships one encounters in life. Because couple and marital counseling deals with two people and the dynamics that exist in their relationship, the

To further develop the professionalism of this emerging field, standards for marriage counseling were published, and marriage counseling was established as a specialty of family counseling in 1949. Signifying the consolidation phase was the first legal recognition of the marriage counseling profession in California in 1963. In 1970 the name of the association was changed to the American Association of Marriage and Family Counselors (AAMFC), and in 1978 it changed again to the American Association for Marriage and Family Therapy (AAMFT).

For many years, most of the attention and focus in the field was on the family; however, over time the couple and marriage counseling movement advanced. In the 1980s, the *Clinical Handbook of Marital Therapy* by Jacobson and Gurman was published and contributed significantly to advancing the specialization of couple and marital counseling. The formative phase saw an increase in the number of education programs offering training specifically on counseling with couples. Additionally, the profession experienced major growth and a subsequent clarification of training standards and competencies for practice. Couple and marriage counseling is now considered a distinct approach with published research with information on the science of the relationship.

### Approaches

There are many approaches to working therapeutically with couples. These approaches differ in focus, process, and goals. A comprehensive review of all theories in the couple and marriage counseling field is too broad for the scope of this entry. However, several will be discussed briefly.

Psychoanalytic couple counseling focuses on helping individuals recognize their own unconscious processes as well as those of their spouse or partner. This theory tries to uncover childhood conflicts that have gone unresolved and are therefore influencing the state of the current relationship. The psychoanalytic couple therapist attempts to understand current interactions and their connection with interactions that occurred at early developmental levels. One of the primary goals of this theory is to encourage each person in the context of the relationship to become a distinct individual self. The psychoanalytic approach views the individual as one who chooses a partner based on dynamics that existed in early parent-child interactions. As with

traditional and individual psychoanalysis, this is a long and intense form of counseling.

Behavioral couple counseling is widely used and thoroughly researched and focuses on observable behaviors. This type of couple counseling focuses on improving the couple relationship by attempting to improve positive exchanges while decreasing negative interactions. Like individual behavioral therapies, behavioral couple counseling views the environment as a major influence on creating and sustaining the intimate relationship. The practitioner applying this theory pays particular attention to the cycles each member of a couple engages in to control the behavior of the other. Homework, assessment tools, and at-home and in-session observations are used regularly in this approach. In general, this is time-limited and symptom-focused counseling.

Cognitive-behavioral couple counseling focuses not just on the behavior of each person in the relationship but on the interpretation that each makes about the other person's behavior. The goal of this counseling is to assist the couple in identifying the thoughts that contribute to the marital problems, to test whether or not the thoughts are valid or accurate, and to modify the thoughts accordingly. For example, when couples use language such as "always" and "never" when talking about each other, the counselor may encourage the couple to seek exceptions related to these statements. A cognitive-behavioral couple counselor might also seek to discover assumptions that are not accurate and assist the couple in discovering more accurate assumptions. For example, if someone believes happy couples never fight, the therapist might help him or her form more accurate assumptions.

Emotionally focused couple counseling views problems in the relationship as relating specifically to attachment. According to this theory, attachment problems that develop in the earliest stages of life interfere with the emotional connection of the relationship, and couples will hide emotions both primary (fear and insecurity) and secondary (anger and defensiveness). Relationship difficulties emerge when the relationship fails to provide security for one or both partners. Often, attachment difficulties lead to additional fears such as abandonment. A focus of counseling using this theory is on the feeling and expression of emotion. Through the expression of emotion, couples are more able to discover functional ways of interacting and ultimately satisfy their need for attachment.

Systemic couple counseling views the couple as a unique system in and of itself. Systems theory examines the context in which individuals live. Whereas individual psychology traditionally focused on internal processes causing problems, systems theory focuses on the family or couple system as the source of problems. Systems theory uses a holistic perspective, meaning the complexity of individuals in the context of their lives is considered when determining a problem's source. The parts of systems interact with each other in a dynamic way, as each element in the system affects the others. A systemic couple counselor might use such techniques as having each person develop a family genogram (a diagram outlining family history and relational patterns) or sculpt family dynamics (a physical representation of couple dynamics and positioning), or the counselor might encourage the couple to discuss myths and stories. Homework assignments for the couple are an important part of this type of counseling.

The field of couple and marriage counseling has grown tremendously over the past 70 years, and in that time, theories related specifically to the treatment of difficulties in couples emerged. Many counselors do not rely on only one theory of counseling but use an integrative approach in response to the couple's needs and to assist couples with many different types of difficulties.

### Unique Process

The increase in divorce rates in the United States is one example of the complexity of an intimate relationship and the challenges in maintaining the intimate bond of a marriage or committed relationship. Often couples enter counseling when they feel they have no other options for maintaining the relationship, creating a greater intensity in the counseling process. It is typical with many relationships that when there are problems, each member blames the other for the problems and may even expect the other to make significant changes to make the relationship work. Because both members in the relationship are invested in being right, each may attempt to establish with the therapist that he or she is right. Therefore it is essential that the counselor remain neutral and objective, honoring the viewpoint of both, as both are the client in this regard. The counselor must recognize the contributions both make to the relationship struggles.

Because couple counseling is dynamic and intense, it requires the counselor to be active and direct. When

negative interactions occur between individuals in a couple, the counselor must block their communications and redirect them to more facilitative, respectful, new patterns of communication. A positive counseling experience allows the couple an opportunity to explore new behaviors and practice the skills they learn.

A consideration unique to couple counseling is whether to see both members together at all times or to explore whether separate individual sessions would at times be helpful. Each couple and marriage therapist makes this decision based on his or her therapeutic approach. Some therapists first see the couple together and follow up with individual sessions to determine individual concerns. Often in these cases the counselor is also seeking to determine individual commitment to the relationship to assess the degree to which the counseling is likely to be successful. Other couple and marriage counselors see couples together only.

Secrets also are an important consideration for the couple and marriage counselor. Specifically, one partner may not be aware of how close the other partner is to ending the relationship, or there may be an undisclosed affair or some other secret that is impacting the relationship. Couple and marriage counselors differ on how to handle secrets in couple and marriage counseling. As mentioned above, some counselors only see couples together to avoid being drawn into a secret. Other couple and marriage counselors are willing to hear secrets so they know the information about the relationship, regardless. Often counselors inform the couples before the counseling begins how they will handle secrets, specifically whether they will reveal the secret to the other partner if a secret is revealed.

### Common Issues

In general, when either person in a partnered relationship views the dynamics in the relationship as problematic, the couple may be appropriate for couple counseling. Although the list of reasons why a couple may seek couple counseling is endless, there are broad categories of problems that are common problems presented by couples.

A study conducted by Whimson, Dixon, and Johnson indicated that communication problems were the most frequently reported difficulties, with power struggles, unrealistic expectations of spouse, sex, and problem-solving being the next most frequently reported problems, in that order. A few of the couple problems that were ranked as most difficult to treat

were a lack of loving feelings, alcoholism, extramarital affairs, and power struggles. There are several problems presented in couple and marriage counseling that require the counselor to make challenging decisions, and these often require a unique set of skills; specifically, these problems are intimate partner violence and extramarital affairs. Couple and marriage counselors face barriers such as secrecy, trust, and safety when working with couples on such difficulties. Additionally, with couples who experience violence in the relationship, secrecy is often an unspoken expectation that creates a large barrier in the counseling process.

### Challenges

The practice of couple and marriage counseling is facing, and will continue to face, unique challenges as the nature of the intimate relationship also changes. Specifically, the field is responding to the demand for a broader definition of *couple* to address the needs of diverse couples. Diversity in relationships refers to cultural and ethnic differences not only between counselor and couple but between partners in the relationship. Diversity also includes religion, sexual orientation, couples remarrying, and the aging of couples. An additional challenge to couple and marital counseling is the prevalence of violence among couples. A call to the profession is to develop more programs for treating violence in the intimate relationship.

## COURTOIS, CHRISTINE A. (1949– )

---

Christine A. Courtois is best known for her pioneering work in understanding, diagnosing, and treating post-traumatic stress disorder (PTSD) in survivors of sexual abuse, particularly incest. Beginning with her graduate studies and continuing throughout her career, she has been groundbreaking in her commitment to the well-being of the patients she serves and to the expansion of knowledge about dissociative disorders and PTSD. She is presently in independent practice in Washington, D.C.

Courtois received her Ph.D. in counseling from the University of Maryland Department of Counseling and Personnel Services in 1979 after completing her internship at the University of Maryland Counseling Center in 1978–1979. Her dissertation (*Characteristics of a volunteer sample of adult women who experienced incest in childhood or adolescence*) and her volunteer work with rape crisis centers during her graduate training marked her entry into the area of sexual abuse and its aftereffects.

After receiving her Ph.D., Courtois moved to Cleveland, Ohio, where she held a staff counselor position at Cleveland State University. On her return to Washington, D.C., she served as a staff counselor at the counseling center at the University of Maryland, as a counseling psychologist at the U.S. General Accounting Office's Counseling and Career Development Center, and as a staff psychologist at the Women's Medical Center of Washington, D.C. In 1983, Courtois moved to independent practice in Washington, D.C., where she maintains her own

practice, with associates, focused on individual and group time-limited and long-term counseling and psychotherapy; clinical supervision and consultation; and international, national, regional, and local training and consultation services on a variety of mental health and organizational topics.

In addition, beginning in 1989 and continuing until 2007, Courtois was a cofounder (along with Joan Turkus) of and clinical consultant for an inpatient dedicated treatment unit for individuals traumatized by abuse and experiencing posttraumatic and dissociative disorders. The original unit (Abuse and Dissociative Disorders Recovery Unit) was founded in 1989 at HCA Dominion Hospital in Falls Church, Virginia. In 1991, the unit was moved to the Psychiatric Institute of Washington (Washington, D.C.) as The Center: Posttraumatic Disorders Program, and a partial hospitalization program was added. Principles of enhancing strengths and empowerment, drawn from Courtois's training in counseling psychology and feminism, serve as the foundational principles for the program.

Although Courtois's primary commitment has been to the highest quality of her own treatment for survivors of trauma (particularly sexual trauma and incest), she also maintains a deep commitment to both scientific and scholarly understanding of sexual assault and its aftermath and to education and training for practitioners, researchers, and theorists. As she has been in the practice arena, Courtois has been tireless and prolific in her contributions in these arenas.

Courtois has written three books on incest and sexual abuse. *Healing the Incest Wound: Adult Survivors in Therapy* was published by W. W. Norton in 1988 with a paperback edition released in 1992 and a Chinese translation in 2002, reflecting the remarkable longevity and impact of this groundbreaking work and making it a classic in the area. In 1993, she published *Adult Survivors of Child Sexual Abuse: A Workshop Model*, and this was followed in 1999 (paperback in 2002) by *Recollections of Sexual Abuse: Treatment Principles and Guidelines*, again published by W. W. Norton. In addition, she has published two special issues of journals (*The Counseling Psychologist: Victimization and Its Aftermath* with James O'Neil in 1988 and *The Journal of Traumatic Stress*, special section on complex trauma, with Bessell van der Kolk in 2005) and numerous book chapters and articles on trauma, traumatic memory, sexual abuse, incest, and recovery with multiple publications every year since

she received her doctorate. She has an extensive history of service on editorial boards and as an ad hoc reviewer as well.

Courtois's commitment to education and training is reflected in both her contributions to scholarly literature and her faculty appointments, which include positions at the Smith College School for Social Work, Harvard Medical School, and Georgetown University. Recently she has worked with the Maryland Psychological Association to develop a Post Doctoral Institute on Trauma and Dissociation. She gives many talks and workshops annually, nationally and internationally.

Courtois's contribution to the profession through volunteer service in professional organizations is no less noteworthy. She has held numerous appointed and elected positions with the International Society for the Study of Dissociation (ISSD), the International Society for Traumatic Stress Studies (ISTSS), and the Society for Counseling Psychology (Division 17) of the American Psychological Association (APA) as well as other appointed positions with the APA, other professional associations, and numerous community organizations.

Courtois's commitment, dedication, and contributions to the field have been recognized many times over. She is a Fellow of APA Divisions 17 (Society for Counseling Psychology), 29 (Psychotherapy), 35 (Psychology of Women), and 42 (Psychologists in Independent Practice) and the ISSD. The awards she has received have been significant. In 1996, the APA presented her with one of its premier awards, the Award for Distinguished Professional Contributions to Applied Psychology as a Professional Practice. She has received the John Black Award (1995) and the Section for the Advancement of Women "Woman of the Year" award (1994) from the Society for Counseling Psychology. The ISTSS awarded her the Sarah Haley Award for Clinical Excellence in 2003, and the ISSD awarded her the Cornelia Wilbur Award in 2001. She was elected a Distinguished Practitioner in Psychology of the Psychology Academy of the National Academies of Practice in 1998.

## CREDENTIALING INDIVIDUALS

---

The credentials and credentialing processes described in this entry are recognitions that a practitioner voluntarily seeks. They provide indications of advanced training and skill as well as evidence that the practitioner has passed certain examinations. All of the credentials described are obtained after a degree has been completed and, in many instances, after a license to practice has been obtained. Credentialing informs the public that counselors not only adhere to a code of ethics and have met minimum requirements of education and experience but have completed advanced training, submitted their professional work for peer review, and/or successfully passed postdegree and postlicensing examinations. The counseling profession demonstrates to the public that the profession is dedicated to setting and meeting higher, self-imposed standards through these credentialing efforts.

### Master's Level Credentials

#### ***National Certified Counselor***

The National Certified Counselor (NCC) is the principal credential of the National Board for Certified Counselors (NBCC). Established in 1982, the NBCC is an independent nonprofit credentialing body for counselors. The NBCC was developed by the American Counseling Association (ACA) and designed to be a separate, independent credentialing body for counselors. The NBCC recognizes counselors who have voluntarily sought to meet standards set by counseling

professionals, not state legislators. Candidates seeking the NCC credential (an NCC credential may be sought at both the master's and doctoral levels) must meet requirements in education, work experience, and supervised experience. They must also pass the National Counselor Examination (NCE).

In addition to the NCC credential, there are three additional specialty credentials offered by the NBCC: the National Certified School Counselor (NCSC), the Master Addictions Counselor (MAC), and the Certified Clinical Mental Health Counselor (CCMHC). Each of these subspecialties is outlined below.

#### ***National Certified School Counselor***

The National Certified School Counselor (NCSC) credential recognizes those school counselors who have voluntarily submitted an application and passed a national examination. The NCSC credential has multiple benefits for a school counselor, the public, and community agencies. This credential promotes counselors' professional identity, holds professionals to a high standard of accountability, encourages professional growth, and heightens the professionals' national visibility.

To receive an NCSC credential, a counselor must

- Hold the NCC credential
- Do additional coursework in school counseling

#### ***Master Addictions Counselor***

In a collaborative effort, the Master Addictions Counselor (MAC) specialty credential was created by the ACA, the International Association of Addiction and Offenders Counselors (IAAOC), and the NBCC. This specialty credential aims not only to encourage professional development but to recognize those who have taken the initiative to meet all national professional standards in addictions counseling. A MAC credential benefits the individual counselor by increasing visibility and professional identity in the community and simultaneously benefits clients by raising counselor standards for training, skills, and accountability.

To receive a MAC credential, a counselor must

- Hold the NCC credential
- Complete additional coursework in the area of addictions

- Have supervised experience as an addictions counselor
- Pass the Examination for Master Addictions Counselors (EMAC)

### ***Certified Clinical Mental Health Counselor***

In 1993, the National Academy of Clinical Mental Health Counselors (NACMH) worked with NBCC to form the Certified Clinical Mental Health Counselor (CCMHC) specialty credential. This credential was created to set standards for competency among professional clinical mental health counselors.

To receive a CCMHC credential, a counselor must

- Hold the NCC credential
- Meet additional educational requirements in counseling, including a supervised practicum
- Have additional supervised work experience
- Pass the Examination of Clinical Counseling Practice (ECCP)
- Submit an audio or videotape of a counseling session for approval

### ***Certified Family Therapist***

Initiated by the International Association of Marriage and Family Counselors (IAMFC), the National Credentialing Academy (NCA) began offering the Certified Family Therapist (CFT) credential in 1994. The CFT credential identifies professionals who have met NCA national standards related to training, experience, and ethics in family therapy. The CFT promotes professional accountability and encourages ongoing professional growth and development of marriage and family counselors. To receive a CFT credential, a counselor must meet one of five distinct combinations of criteria. The combination varies depending on

- The candidate's graduate degree
- The candidate's supervised experiences as a marriage and family therapist (e.g., as evidenced by state licensure requirements)
- The requirements the candidate has met in an accredited graduate program
- The candidate's clinical membership in the American Association of Marriage and Family Therapists (AAMFT)

In addition, two references or endorsements are required.

### ***Certified Rehabilitation Counselor***

The Commission on Rehabilitation Counselor Certification (CRCC) was chartered in 1973 as a non-profit organization designed to establish standards for the profession of rehabilitation counseling and improve the quality of care to persons with disabilities. Those professionals credentialed as a Certified Rehabilitation Counselor (CRC) have demonstrated good moral character and a minimum level of competency based on nationwide standards of professionalism set by the CRCC. The CRC credential recognizes those counselors who have the training and experience to provide vocation, person, or socialization counseling to persons with disabilities. To be eligible for the CRC credential, the professional must meet one of six sets of criteria that include

- A master's or doctoral degree in counseling or rehabilitation counseling
- Specific coursework in rehabilitation counseling
- Supervised internship or acceptable employment experience

## **Doctoral Level Credentials**

### ***American Board of Professional Psychology***

The American Board of Professional Psychology (ABPP) was formed in 1947 with the support of the American Psychological Association (APA). Since that time, the ABPP has become a separate entity and is a unifying governing body for separately incorporated specialty boards. The ABPP identifies a specialty as "a defined area in the practice of psychology that connotes specialty competency acquired through an organized sequence of formal education, training, and experience." Counseling psychology, of course, fits this definition. Presently, there are 13 specialties recognized by ABPP.

The specialty of counseling psychology is represented within the ABPP by the American Board of Counseling Psychology (ABCoP) and the American Academy of Counseling Psychology (AACoP). The AACoP has three primary functions. First, it advocates for the profession of counseling psychology within legislative and other governmental bodies, such as state licensing boards. Second, it has an education role both in terms of educating the public and providing continuing education for board certified counseling psychologists. Third, it is primarily responsible for

marketing, recruiting, and mentoring qualified counseling psychologists into and through the application and examination process.

The ABCoP is primarily responsible for developing and implementing the examination process that leads to board certification in counseling psychology. The ABCoP accepts applications for board certification from counseling psychologists who provide a variety of professional services, including psychotherapy in private, educational, medical, or governmental settings; career and vocational interventions; teaching or supervision of core counseling psychology courses; consultation; and academic administration or counseling.

The examination process has three stages. First, counseling psychologists must submit their credentials to ABCoP in order to prove that they have the appropriate educational background, training, and work experience to qualify as practicing counseling psychologists. Candidates may meet the education requirement in the following ways:

- Holding a doctoral degree in professional psychology accredited by the American Psychological Association (APA) or the Canadian Psychological Association (CPA)
- Completing a program listed in the publication *Doctoral Psychology Programs Meeting Designated Criteria*
- Completing a designated program of the National Register of Health Services Providers or in the Canadian Register of Health Service Providers
- Holding a current Certificate of Professional Qualifications in Psychology (CPQ)
- Holding a degree in psychology and completing postdoctoral study to receive a license to practice psychology in a recognized jurisdiction in the United States or Canada.

Additional requirements include the following:

- A current license to practice psychology in the jurisdiction in which the psychologist lives (an exception for this requirement is granted to active duty military psychologists)
- Completion of a predoctoral internship
- Completion of 1 year of postdoctoral supervision
- At least 2 years of postlicense experience

Once the counseling psychologist's credentials have been verified, he or she is advanced to the Practice Sample stage of the process. This stage requires

a professional self study (PSS) and a case study (CS). The PSS is a personal narrative of one's theoretical, philosophical, and/or personal approach to the practice of counseling psychology. It is expected that this narrative will include mentions of professional articles, books, or mentors that have influenced the applicant's work and ideas as well as descriptions of experiences in training, background, and practice that have informed the applicant's approach to counseling psychology practice. The requirements for the CS are determined by the competency area in which the applicant is submitting his or her professional expertise and vary depending upon whether the case to be used for the sample involves an individual client, the supervision of another psychologist or trainee, a career or vocational intervention, or a demonstration of the role of a counseling psychologist in an administrative setting. Any situation in which a clinical intervention is submitted as a case requires a videotape to accompany the CS.

The PSS and CS are reviewed by two board certified counseling psychologists; once these studies have been accepted, the applicant is invited to attend the oral examination, at which a number of applicants will be examined on the same day. The oral examination is a day-long process that includes five areas of competency. Each section of the examination typically includes two examiners. The areas covered by the oral examination are assessment, intervention, consultation and supervision, ethics, and professional issues.

The ABCoP also provides a Senior Option for psychologists who have been licensed and practicing for more than 15 years. In general, the Senior Option allows the applicant to substitute his or her published works or professionally developed, implemented, and documented programs for the CS.

### ***Certificate of Professional Qualification in Psychology***

The Association of State and Provincial Psychology Boards (ASPPB) is a professional organization of psychology licensing boards in the United States and Canada. The purpose of the Certificate of Professional Qualification in Psychology (CPQ) is to address the problem of license mobility across states and Canadian provinces. Because state and provincial licenses are not widely recognized outside the jurisdictions in which they were issued, the ASPPB sought to find a way to facilitate the normal and expected movement of psychology professionals from one

licensing jurisdiction to another. The CPQ was established in 1998 with two primary strategies to meet this goal. First, licensed psychologists who meet established criteria are issued a certificate (CPQ). Second, a credentials bank has been created in which individuals may store the documents demonstrating their eligibility for licensure, and it may be used by licensing boards to determine the requirements an individual must meet for licensing in their jurisdiction. To receive a CPQ, applicants must

- Meet educational requirements in psychology
- Have a current license to practice psychology
- Have a history of supervised experience
- Pass the examination for professional practice in psychology (EPPP)
- Pass an oral examination or interview related to competence to practice
- Have at least 5 years of postlicense experience
- Have no history of disciplinary actions

Psychologists who do not meet the requirements of the CPQ may store their license-related materials in the credentials bank and then ask the ASPPB to forward these materials to any jurisdiction. The CPQ, of course, is not a license to practice and does not automatically guarantee that a licensing board will accept the credentials presented, but the ASPPB does advocate with boards to accept the CPQ as evidence that basic requirements for licensure have been met. ASPPB member boards may have additional requirements, and any applicable fees must be paid in that jurisdiction.

### ***Certificate of Proficiency (Treatment of Alcohol and Other Psychoactive Substance Use Disorders)***

The American Psychological Association Practice Organization's College of Professional Psychology developed Certificates of Proficiency in order to recognize licensed psychologists whose scope of practice includes the treatment of alcohol and other psychoactive substance use disorders. This certification is designed to demonstrate that a professional has the specialized training in chemical abuse disorders that is frequently required by health maintenance organizations, preferred provider organizations, and some legislative jurisdictions. The Certificate of Proficiency has been accepted as evidence that the psychologist is qualified to offer these specialized services. The

certificate provides national, uniform documentation that a psychologist

- Has a current license to practice psychology
- Has at least 1 year's experience treating chemical abuse disorders (within the last 3 years)
- Is an active health service provider
- Has passed the college of professional psychology's examination in alcohol and other psychoactive substance use disorders

### ***National Register of Health Service Providers***

The National Register of Health Service Providers is a membership credentialing service that has, for more than 30 years, provided a list (register) of qualified psychologists both to the public and to health services providers. A Health Service Provider in Psychology is defined by the register "as a psychologist, certified/licensed at the independent practice level in his/her state, who is duly trained and experienced in the delivery of direct, preventative, assessment and therapeutic intervention services to individuals whose growth, adjustment, or functioning is actually impaired or is demonstrably at high risk of impairment."

The register verifies the credentials submitted from prospective members for healthcare providers. To be listed in the register, applicants must comply as follows:

- Have a doctoral degree in psychology that is accredited by the American Psychological Association (APA) or the Canadian Psychological Association (CPA) or have completed a program designated as meeting criteria established by the Association of State and Provincial Psychology Boards (ASPPB) or have completed a doctoral program in psychology designated by the National Register of Health Services Providers
- Have completed a minimum 1-year predoctoral internship (1,500 hours)
- Have completed a minimum of 1 year of postdoctoral supervision (1,500 hours)
- Hold a current license to practice psychology
- Provide an official transcript from the doctoral degree-granting institution
- Demonstrate that they have been subject to no disciplinary actions

In addition to its credentialing function, the register provides a number of services to its members,

including licensure mobility, continuing education, and publication of *The Register Report*, and it acts as an advocate for psychologists' practice concerns with legislative bodies. The register also recognizes psychologists' achievements through awards and other forms of recognition. The National Register is one of the most widely recognized credentialing bodies in the United States and Canada, and its credential is accepted by most healthcare organizations in identifying healthcare providers qualified to practice psychology.

## CUSTODY EVALUATIONS

A child custody evaluation, also known as a parental responsibility evaluation, is a process by which recommendations are made to a family court with respect to the best interests of a child. They may include responses to parents' requests for parenting time or access to their children as well as evaluations of who should have decision-making authority regarding the child's education, health care, and religion. Such evaluations are performed by qualified mental health professionals who have been appointed or recognized by a family court or by privately qualified mental health professionals. Typically, the need for such an evaluation arises where there has been a high-conflict divorce; where there are accusations regarding one or both parents' parenting practices; where there are concerns about a parent's mental health problem, child abuse, or substance use or abuse; where the primary care parent is relocating, or in any other circumstances that may have a negative impact on the child's best interest. While divorce rates in the United States remain high, about 90% of child custody disputes are settled out of court. The remaining 10% often involve protracted litigation.

### Historical Perspectives

From colonial times until about the middle of the 1800s, child custody decisions were based upon British common law. These laws were gender biased and gave custody to fathers based upon paternal entitlement. This practice continued until around the time of the Industrial Revolution, when women's groups began protesting these laws. By the 1880s, most states had adopted the *tender-years doctrine* for custody decisions. The tender-years doctrine basically stated that when all other factors are equal, children under the age of 13 should reside with their mothers. If fathers wanted to retain custody, they had to prove that the mother was unfit or had committed adultery. The fitness of parents was heavily influenced by the perceived morality of the time. This often resulted in discrimination against homosexual or cohabiting parents.

Starting in the mid-1960s, the *best-interest doctrine* was adopted as a gender-neutral, child-centered model for custody decisions. The Uniform Marriage and Divorce Act, passed in 1974, attempted to standardize best-interest criteria. The criteria included

consideration of the wishes of the parents and child, the physical and mental health of all parties, parent-child interactions, the child's adjustment in multiple areas of life, and any special matters relevant to parental fitness. The first joint custody statute was passed in North Carolina in 1957, but due to lack of a favorable reception, records show shared parenting rulings were not widely recognized until the 1980s. Recent studies by the American Bar Association have shown that the number of sole custody decisions has decreased dramatically since that time, and joint custody is a far more common outcome. In most cases, permanent physical custody is awarded to the parent with whom the child will live the majority of the time. The custodial parent will have joint custody with the noncustodial parent, and they will share important decisions related to matters such as health care and education. In most cases the courts will also order scheduled visitation or temporary custody to the non-custodial parent.

The best-interest doctrine has increased attention to children's emotional and developmental needs when making custody decisions and has necessitated the involvement of mental health professionals in custody disputes. In fact, the best-interest standard has replaced parental preference, thus allowing child custody to be granted to grandparents as highlighted by the landmark case of *Painter v. Bannister*.

By law, custody evaluations are supposed to answer the question of what outcome is in the best interest of the child. That is the standard for all jurisdictions in the United States, and it serves as the basis for the judge's custody and visitation decisions. Therefore, it is important that custody evaluators be impartial and avoid advocating for either parent. The assessment goals are to identify the developmental needs of the child, to highlight strengths and needs of all parties, to observe and collect information pertaining to interactions of all relevant parties with children, and to develop a plan reflecting the best interest of the child.

Methodologies vary from one evaluator to the next; however, all evaluators must collect enough data to make their recommendations referencing the family court statutes criteria on best interests of the child. A thorough evaluation involves home studies, clinical interviews, clinical assessments, and self-reporting from involved parties as well as interviews or case notes from collateral contacts to substantiate the evaluator's recommendations. Collateral contacts may be anyone from family members to experts. Examples of

individuals listed as collateral contacts are teachers, school administrators, counselors, psychiatrists, medical doctors, social service personnel, parole officers, and court-ordered supervisors for parenting time.

The assessment tools used in custody evaluations can vary; however, the two most popular testing assessment tools used today in custody evaluations are the Minnesota Multiphasic Personality Inventory-2 (MMPI-2) and the Millon Clinical Multiaxial Inventory-III. The evaluator will use profiles that emerge from the assessments along with the parties' self-reports and the background offered by collaterals to evaluate and respond to the statutes' criteria and subsequently formulate recommendations.

In addition to the criteria identified in the best-interest standards, the court may also ask the evaluator to investigate specific issues (e.g., drug or alcohol abuse, domestic violence, special needs of a parent or child.) The evaluator will then be ordered by the court to report on the specifics of the recommendations. The order from the court has three areas of investigation: allocation or modification of parenting time, allocation or modification of decision-making responsibilities, and relocation of the primary residential parent. The court may order the evaluator to investigate all pertinent issues identified and make recommendations on any or all of the above areas. The recommendations from the evaluator are submitted to the court as well as to the involved parties either *pro se* or through counsel via mail within 90 to 120 days of the initial court order. Once the recommendations are submitted, the evaluator is considered to have completed the case, unless he or she is summoned into court by subpoena as an expert witness.

## DEATH AND DYING

---

Death describes the cessation of life, and dying speaks to the manner in which death occurs. Although these are simple concepts to understand intellectually, the realms of personal experience and counseling to which they refer are quite complex. As noted by Schneiderman, death entails many contradictions given the various ways in which it may be perceived. For some death is the destroyer, for others it is a redeemer. Similarly, it may be seen as both the greatest cruelty and as a means of release. Whereas fear of death tends to be universal, there are those who actively pursue it. Despite the reality that all are subject to death, each person's experience is unique. We live with the fact of our death from the moment of birth and yet have little knowledge of the phenomenon. We thus tend to be fascinated by the subject even as we fear it.

### Societal Perceptions

During the 19th century, the worlds of the living and of the dead generally were closely intertwined, with meaning flowing freely between them. However, as advances in medical technology and health care during the 20th century led to dramatic improvements in birth survival rates and exponential increases in life expectancy, a hope that death might eventually be conquered evolved. In the West, this hope gave birth to a culture that, until very recently, was reluctant to embrace death as either an integral part of life or a phenomenon to be studied and understood. Ours has been described as a death-denying society, with fear

the norm and perceptions of death so negative that it is a topic studiously to be avoided.

Many explanations have been offered regarding the desire to bypass conversations about death. These include the fear that talking about death will encourage or bring it forth and the related thought that avoiding the subject will preclude its appearance. Additionally, most have great concerns about the dying process as well as the inevitable unanswered questions about what happens after they die and distress at the thought of losing the one life we are given. Awareness of a lack of meaning in our lives, negative associations around the decay of our bodies, apprehension about judgment, dread of the unknown, and fear that nothing awaits us on the other side of death all lead to a general sense of trepidation. Despite such pervasive attitudes, however, within the mental health professions the topic of death and dying has become an important area for consideration.

### Professional Developments

The late 1960s and early 1970s were a highly volatile era in our social history, characterized by significant growth in awareness of and responses to the previously unmet needs of those who were dying. The concepts of hospice and palliative care were pioneered in England by Dr. Cecily Saunders, and in the United States, Dr. Elisabeth Kübler-Ross was at the forefront of the field of thanatology. The evolution of a new movement was marked by the first meeting, in 1974, of what eventually became the International Work Group on Death, Dying and Bereavement. In 1976, in response to the needs of a growing number of professionals

involved in this work, the Forum for Death Education and Counseling, subsequently renamed the Association for Death Education and Counseling, was created. Today, many books, journals, conferences, and training opportunities on the many aspects of death and dying are available, and a variety of research investigations have shed a great deal of light on this subject.

### **Interpretations of Death**

Kastenbaum proposed that interpretations of death may be understood on a continuum that proceeds from its perception as a diminished mode of life and continues to the idea of personal existence continuing much as usual; to its being construed as part of an ongoing process of spiritual development; to its perception as a progression composed of the three phases of waiting, judgment, and eternal culmination; to the notion of recycling as one is born, dies, and is reborn again and again; and to the idea of death as nothingness. In addition to the need to acknowledge individual interpretations of death, we now also recognize the importance of understanding the many ways in which death and dying can occur.

### **Unexpected Death**

When death is unanticipated, persons who have died may have made no arrangements nor had an opportunity to express their wishes regarding such issues as organ donation, funeral arrangements, and burial preferences. Survivors of this type of death tend to experience lack of closure, having had no opportunity for farewells and often being left with feelings of guilt regarding unresolved conflicts. They may experience acute feelings of unreality, disbelief, shock, and a sense of many loose ends. Additional ramifications may include dissonance in terms of beliefs and meaning systems, particularly if the death occurred under tragic circumstances or involved the loss of a child. In the latter instance, the feeling of a death out of time may be extremely significant. A further complicating factor for survivors relates to the type of unanticipated death experienced.

### **Accidents**

Guilt for not having done things differently, and thus somehow being involved in causing the fatality, is typical following death by accident, given the connotation of chance or fluke associated with this term.

Irresponsibility on the part of another who contributed to the death also may add complexity, especially when not acknowledged appropriately.

### **Physical Problems**

Sudden death caused by a physical problem may lead to the perception that it could have been prevented. Survivors thus may tend to blame themselves or others for not having responded properly.

### **Violent or Wrongful Death**

Survivors may worry about the suffering experienced by victims of violent or wrongful death in the process of dying. They may rage about the injustice at the same time that they have to deal with disfigurement or mutilation of the body of the person who has died. Involvement with the media or the legal system may prolong their agony.

### **Suicide**

Those left behind in the wake of a completed suicide typically desire privacy. They may have guilty feelings and experience an inability to speak about the death given the social stigma involved.

### **Anticipated Death**

With anticipated death, dying persons may put their affairs in order, participate in funeral arrangements and burial decisions, and achieve closure in significant relationships. They also have an opportunity to assimilate what is happening and realign their beliefs and meaning systems. At the same time, foreknowledge tends to initiate a period of anticipatory mourning for everyone involved. Further, in an extended dying process, significant stress may be placed on caretakers, and dying persons may feel a sense of remorse about being a burden. When the sick person dies, feelings of relief may be accompanied by feelings of guilt for what are perfectly normal, if mixed, reactions. Throughout the dying process, many additional issues also may require attention.

### **Acknowledging Death**

An important task faced by dying persons involves coming to terms with imminent death. Kübler-Ross

described this process as involving the five stages of denial, rage, bargaining, depression, and acceptance. However, it is unlikely that all dying persons go through each stage, or that they necessarily follow the same sequence of emotions. Indeed, many have little or no trouble accepting the fact of their dying, experiencing it in a variety of ways.

Once the inevitability of imminent death is acknowledged, issues around how a person wishes to die arise. If the person prefers to die at home, hospice may be an option. Advocates of hospice believe that supportive, palliative care until physical death has been medically determined is the most appropriate response to a terminal diagnosis. However, candidates for hospice must meet criteria pertaining to the anticipated time until death and the presence of appropriate caregivers. When hospice is not an option or not preferred, the choice may be to die in a hospital and often to continue treatments aimed at cure until all efforts in that regard have been exhausted.

### The Impact of Technology

The development of highly sophisticated technology, including various life-support systems and advancements in the realm of organ transplantation, has greatly enhanced the ability of medical science to prolong life. Given these developments, both the medical and legal communities often struggle around questions regarding when death has occurred and when life-prolonging mechanisms should be discontinued. One of the earliest efforts to alleviate confusion involved the delineation of the differences between a vegetative state and brain death.

A set of standards, formulated in 1968 by a group of physicians at the Harvard Medical School and now known as the Harvard Criteria, has become the means for determining when the brain has reached a condition in which it is considered to be irreversibly non-functional. Accordingly, death is understood to have occurred when the patient is unresponsive and unresponsive, there is no spontaneous respiration or muscular movement, the usual reflexes are absent, the brain is devoid of any electro physical activity, and there is no circulation of blood to or within the brain.

In addition to standards used as a basis on which to make difficult decisions, the field of bioethics has evolved. Those who work in this realm seek to formulate appropriate responses to dilemmas around the use or withdrawal of medical treatment. The overarching

goal is making morally and ethically prudent decisions in the face of biotechnology that has advanced to the point that the boundary between life and death often is blurred.

### Euthanasia

Euthanasia is the intentional termination of life by someone at the request of the person who is dying, while assisted suicide refers to the provision of help to patients at their request so they may terminate their own lives. In the medical realm, *voluntary active euthanasia* (VAE) occurs when the physician gives a medication or somehow intervenes to cause death at the request of the patient; *physician-assisted suicide* (PAS) occurs when the physician provides either information, resources, or direct assistance but the patient terminates her or his own life; and with *physician aid-in-dying*, the physician discontinues treatment at the request of the patient.

Despite the various ways euthanasia may be construed and implemented, Oregon is the only state in which PAS is legal. Although there are no states in which either suicide or attempted suicide is prohibited, 36 states have statutes according to which assisted suicide is a criminal act. In seven states, assisted suicide is a criminal act through the common law, and in six other states, the laws around assisted suicide are unclear. However, according to the U.S. Supreme Court, there are two constitutionally permissible means of alleviating pain for dying persons when all other methods fail: When these persons are treated with either a "morphine drip" administered at a level to eliminate pain or with "terminal sedation" that produces continuous anesthesia, death ultimately will occur. Patients become eligible for such procedures by means of advance directives prepared in compliance with state law and legally witnessed or notarized.

### Advance Directives

The validity of advance directives varies by states, although many have followed California in enacting living will statutes and other legislation that focuses on procedures that have the goal of prolonging life. Passed in 1976, the California Natural Death Act permits individuals, in specific situations, to make prior plans for treatment at the end of life. This statute legally sanctions advance directives and also "protects physicians from being sued for failing to treat incurable illnesses."

According to the federal Patient Self-Determination Act of 1990, healthcare providers must give patients information about their right to make advance directives, have written institutional policies regarding advance directives, and document whether or not a patient has executed one. Advanced directives include instructions regarding end-of-life decisions, ideally made prior to serious illness. They may be designed as either a living will or a healthcare proxy. Living wills detail instructions regarding desired medical intervention should persons become incapacitated. With a health care proxy, created by means of a durable power of attorney, persons designate someone to be responsible for making health care and treatment decisions in the event of future incapacitation.

Advance directives may focus on either clinical conditions or the values history. With the former, the circumstances under which persons would or would not want to live are specified. With the latter, the circumstances under which life is not preferred, even when further medical treatment is available, are described. In either case, persons creating advance directives must be competent and able to understand what they are doing, act voluntarily, be fully informed regarding all ramifications, and freely give consent to implementation. Ethnic and cultural variations and values should be taken into consideration, documents must be internally consistent, and they must focus only on those dimensions included within the scope of standard medical practice.

### Nearing Death Awareness

Hospice nurses have noted that as those who are terminally ill move closer to death, they may experience visions or sense the presence of departed loved ones, spiritual beings, or a bright light, or they may experience awareness of being in a particular place. They may report sensations of great warmth and love. They may attempt to communicate important messages to family, friends, and other caregivers. Engaging in a life review is also likely. While dying persons generally have little fear as the end approaches, there often is great concern about those who will be left behind.

## DELWORTH, URSULA (1934–2000)

---

Ursula Delworth was a pioneer in many ways in counseling and counseling psychology. In fact, she was one of the early counseling psychologists who easily made her home in both counseling and psychology, and her contributions were outstanding in both professional domains.

Delworth was the first of two daughters born to a U.S. naval officer and his wife in 1934. She received a bachelor's degree from California State University, Long Beach in 1956 and worked for several years in school guidance and counseling. She then chose the University of Oregon for her doctoral study in counseling psychology, and she earned her Ph.D. in 1969. Her dissertation compared the work of members of a

group of professional counselors and counselor support personnel conducting group counseling with students of junior high school age. This research interest was paralleled by activities during graduate school as educational director of Anytown USA, a peer support network in Los Angeles, California.

Her professional career began with an appointment at the Counseling Center of Colorado State University. At that point in time, unrest over civil rights was at a peak, and Delworth began her lifelong interest in outreach, using outreach teams on campus to address racial tensions. She continued that interest with her next professional appointment to the Western Interstate Commission on Higher Education, where she provided training and consultation to many institutions of higher education on the use of campus mental health systems and prevention and outreach programs.

Delworth joined the faculty at the University of Iowa in 1976. She served as director of the counseling center there and as a faculty member in the counseling psychology program, where she supervised many students and served as an encouraging mentor to many more who may have had other advisors but counted on Delworth for support and direction. Her research interests were in supervision, consultation, outreach, and prevention, and she published widely in these areas.

Within the fields of counseling and psychology, Delworth was a passionate advocate for change, and change for the better. She took on issues of equality, diversity, the rights of women and underserved populations, students, early career professionals, and the like with commitment, enthusiasm, and activism. She nominated people for awards, advocated for positions for them within the profession, and mentored many new professionals. Her achievements were recognized with a variety of awards: the Contribution to Knowledge Award from the American College Personnel Association, the Outstanding Contribution to Literature Award from the National Association of Student Personnel Administrators, and the Leona Tyler Award from the Counseling Psychology Division of the American Psychological Association (APA); she was also named one of the 100 Outstanding Women in 100 years of APA.

Perhaps one anecdote illustrates her vibrant commitment to those she believed were under-recognized and underserved. During her year as president of Division 17 of the APA, she began several projects to recognize and promote early career psychologists. Her presidential address that year focused on the need

to mentor and encourage those in the beginning stages of their careers. At the end of the talk, she invited all in attendance who had just earned their degrees to join her at the upcoming social hour, where she would personally buy each of them a drink. And she did! And she was surrounded by a happy, chattering group of new professionals who, it is believed, saw a bright future in counseling.

Her death in May of 2000, literally a month away from her retirement, cut short a life that would have clearly kept on giving to psychology, to counseling, and to her own community. She is deeply missed still by colleagues and friends.

## DEPARTMENT OF VETERANS AFFAIRS

---

The Department of Veterans Affairs (VA) operates the largest integrated healthcare delivery system in the United States. Counseling has had an important and increasingly prominent role in the VA healthcare system since its establishment over 60 years ago. Administered by the Veterans Health Administration (VHA), the VA healthcare delivery system contains the nation's largest mental healthcare system. The VA is the largest provider of mental health services in the country and is among the nation's largest employers

of psychiatrists, psychologists, social workers, and mental health nurses.

To meet the diverse psychosocial needs of veterans, the VHA provides a full spectrum of counseling services, including individual, group, and family psychotherapy; intensive case management; vocational rehabilitation; medication management; psychoeducation; skills training; psychological, cognitive, and neuropsychological assessment services; and psychosocial rehabilitation (PSR) for veterans with serious mental illness. Counseling services (and related psychological services) provided by VHA emphasize evidence-based approaches to a variety of mental health and substance use disorders (including comorbid conditions) and behavioral medicine conditions (e.g., smoking cessation, sleep disturbance, weight management, medical adherence) and to facilitate readjustment to and maximum functioning in the community.

Counseling services are provided to veterans in both VA medical centers (VAMCs) and in VA community-based outpatient clinics (CBOCs). As of January 1, 2007, there were 155 VAMCs and over 700 CBOCs. In addition, a range of readjustment counseling and outreach services (e.g., bereavement counseling, military sexual trauma counseling, vocational counseling, referral services) are provided to veterans and eligible family members in 209 VA Vet Centers located in all 50 states, the District of Columbia, Guam, Puerto Rico, and the U.S. Virgin Islands.

### **Continuum of Care**

Counseling services in VHA are provided across the full continuum of care, including inpatient and residential settings, outpatient mental health and behavioral health settings, and general and psychiatric long-term care settings. Within the inpatient sector, the VHA provides a large array of individualized counseling and related services. In addition to services provided in general and psychiatric hospitals and psychiatric intensive care units, the VHA provides 24-hour therapeutic treatment in psychosocial residential rehabilitation treatment programs to patients with severe mental health symptoms requiring care in a residential setting. Mental health residential treatment services are also provided in VA domiciliaries, which provide homeless veterans with coordinated rehabilitative clinical care in a structured residential treatment setting. In addition, a variety of counseling services are provided to older and younger veterans in VA nursing

homes and other long-term care settings as well as in hospice and palliative care settings.

In recent years, the VA has placed increasing emphasis on community-based mental health care and support services in an effort to promote independence and recovery and reduce the focus on acute stabilization and rehospitalization, even among the most seriously mentally ill veterans. As part of this effort, the VHA has established the Mental Health Intensive Case Management (MHICM) program, which provides evidence-based psychosocial and community support services to veterans with serious mental illness, based on the Assertive Community Treatment (ACT) model. MHICM teams travel to patient homes and throughout the community providing a variety of individualized services to improve patient functioning, community adjustment, and quality of life as well as to reduce hospitalization.

Outpatient counseling services are provided in a variety of specialty settings, including those for mental health, behavioral medicine (e.g., psycho-oncology, smoking cessation), primary care, and rehabilitation (e.g., spinal cord injury, blind rehabilitation). As a comprehensive integrated delivery system, the VA provides unique opportunities for providing interdisciplinary care, which often leads to enhanced safety, efficiency, and clinical outcomes. In many of the outpatient and inpatient settings where counseling services are provided, VA mental health staff serve as active, fully integrated members of treatment teams. This model of care is different from more traditional, fragmented approaches to providing counseling services. The VA's systemwide electronic medical record system further promotes professional coordination and collaboration in the delivery of care.

### **Research and Training**

In addition to providing health care to veterans, a major part of the VA's mission involves conducting clinical research and providing education and training to healthcare professionals and trainees. These functions have become major VA roles in the area of mental health. The VHA is currently a national leader in research on mental illness and mental health treatment. In 1998, the VA established the first three mental illness research, education, and clinical centers (MIRECCs) to conduct clinical research and provide education to promote best practices in VA mental health care. There currently are 10 MIRECCs, each

with a specific area of focus (e.g., substance abuse, causes of serious mental illness, schizophrenia, suicide prevention). In addition, VA geriatric research, education, and clinical centers (GRECCs), which now total 21, work to promote quality of life and care for aging veterans. The VA National Center for Posttraumatic Stress Disorder (NCPTSD) promotes research on and treatment of PTSD and stress-related disorders and is widely recognized as a world leader in PTSD research, education, and training. In addition, the VA has several mental health Centers of Excellence that conduct cutting-edge research in mental illness, posttraumatic stress, and substance abuse.

The VA is the nation's largest provider of clinical training in mental health care delivery, offering practicum training, predoctoral internships, residencies, and postdoctoral fellowships at VA medical facilities throughout the country. Between 1946 and 2005, the VA funded approximately 36,000 training positions in psychology alone. During the 2006–2007 training year, approximately 11% of all psychology predoctoral internship positions and 11% of postdoctoral fellowship positions were in VA facilities.

The VA's roles in conducting innovative clinical research, delivering high-quality care, and providing broad clinical training are enhanced by the agency's close working relationship with the academic community. VA medical centers throughout the country collaborate closely with universities and academic medical centers in each of these three areas. The intellectual and resource partnership has spawned a very successful long-term and mutually beneficial relationship.

### Transformation of Care

To most effectively meet the current and anticipated mental health needs of veterans, the VA is in the process of transforming its mental health care delivery system. In April 2002, President George W. Bush's Executive Order 13263 created the President's New Freedom Commission on Mental Health and charged it with conducting a comprehensive study of the U.S. mental health care delivery system and with providing the president with recommendations for improving the service system. In July 2003, the commission issued its final report, in which it called for a transformation in the nation's mental health care delivery system to improve service access and quality. In July 2003, the undersecretary for health of the VHA charged a workgroup to review the New Freedom Commission's final

report "to determine the relevance of the Commission's goals and recommendations to veterans' mental health programs and to develop an Action Plan that is tailored to the special needs of the enrolled veteran population." This effort led to the development of the VHA action agenda: "Achieving the Promise: Transforming Mental Health Care in America." In June 2004, a mental health task force was established to operationalize the goals and recommendations outlined in the VHA action agenda. This culminated in the development of a comprehensive VHA mental health strategic plan (MHSP): "A Road Map for Transforming VA Mental Health Care." Since 2005, VHA has implemented over 40 mental health enhancement initiatives, which directly implement key provisions of the MHSP. Among the most significant and unique aspects of the MHSP and the mental health enhancement initiatives is the focus on innovation and expanding the process of care.

In an effort to increase access to high-quality mental health services and promote care coordination, the VHA has developed a national initiative to integrate mental health services in primary care. This model of care is designed to break down the traditional "silos" of specialty mental health and primary care settings and allow highly specialized resources to be concentrated on serving veterans with more serious mental health needs. As part of the MHSP, the VHA is also promoting the delivery of evidence-based psychological treatments throughout the VA health care system. The VHA is implementing several dissemination initiatives designed to increase the availability of state-of-the-art psychological treatments for PTSD (e.g., cognitive processing therapy, prolonged exposure therapy) and other mental health conditions.

Also consistent with the recommendations of the President's New Freedom Commission report and the MSHP, the VHA is moving toward a *recovery-based* model of care for veterans with serious mental illness. In the recovery-oriented treatment culture, the focus of care is on instilling hope, optimism, and individual potential through a process of psychosocial rehabilitation. Several VHA initiatives have been developed to expand psychosocial rehabilitation services throughout the VA healthcare system.

Several initiatives are also underway to reach historically underserved populations, such as individuals living in rural areas and older adults with chronic and disabling medical conditions. As part of this effort, the VHA is expanding the availability of telehealth services for veterans in remote areas and is enhancing

specialty mental health staff throughout the country to provide mental health assessment, treatment, and prevention services in the homes of homebound veterans with chronic and disabling medical conditions.

Among the VA's highest current priorities is effectively providing for the mental health needs of returning veterans serving in the Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF) conflicts. In addition to the initiatives noted above designed to increase access to and quality of mental health services, several outreach, screening, and treatment initiatives have been implemented with a specific focus on OEF/OIF veterans. Providing individualized, effective, and accessible care to these and all veterans in the years ahead is a challenge that the VHA is actively meeting. Significantly, with the implementation of the MHSP, there has been a steady increase in the number of mental health providers employed by the VHA. As of January 1, 2007, the VA employed over 9,000 front-line mental health providers.

In short, counseling has enjoyed a rich and continuously evolving history in the Department of Veterans Affairs. Over the course of its 60-year existence, the VA has become widely recognized as a world leader in mental health care delivery, research, and training. With the nation's largest integrated healthcare system, the VA provides unique opportunities for providing innovative, interdisciplinary mental health services in a wide variety of treatment settings. In the years ahead, the mental health care landscape in the VA will continue to evolve, as the VA works to transform the process and culture of mental health care to ensure the availability of accessible and effective mental health services for the veterans of today and tomorrow.

## DEVELOPMENTAL DISORDERS

---

The field of developmental disorders has experienced multiple scientific and social changes in the last decade. Many changes involve the perception of disabilities and have been referred to by Dennis Harper as a shift in paradigms. Some of these changes in the definition of developmental and learning disorders have resulted in changes in societal responses to children and adults with disabilities. In addition, advances in neuropsychological research, imaging, and genetics have refined researchers' understanding of developmental and learning disorders.

### Definition of Developmental Disorders

The implications of developmental disorder classification and resultant diagnostic labels have a major impact on diagnostic systems, scientific study of developmental disorders, and service-based educational intervention and treatment programs for children and youth. The largest impact on children and youth is related to how such definitions become incorporated into administrative rules for the delivery of special education services in schools and related supports in community-based rehabilitation and treatment settings.

Early definitions of developmental disability are relevant to the understanding of the current status of developmental disorders. The earliest definitions of developmental disabilities were crafted in Public Law 91-517 in 1970. This law was an outgrowth of the work of several forward-thinking individuals who assisted on the president's panel on mental retardation at the request of President John F. Kennedy in 1961. This effort was directed toward prevention in mental retardation worldwide. This panel and its outcomes set the stage for subsequent legislation related to developmental disabilities and later, developmental disorders. This presidential panel made important contributions that expanded early definitions and approaches to the treatment of developmental disabilities. These contributions included keeping children with disabilities in their

normal or local environments; supporting those with physical impairments; encouraging a blended continuum of medical, educational, and social care throughout the life span; recognizing a coordinated, interdisciplinary treatment approach; focusing intervention on local and state levels; and encouraging coordination between university medical professionals and state provider agencies. This panel laid the structure for many important aspects of defining and treating developmental disorders in the next several decades.

Over the next three decades (1970–2000), the definition of developmental disabilities changed in scope and complexity. Most important, in 1975, Public Law 94-103 broadened the developmental disabilities definition to include autism and a few specific learning disabilities (e.g., dyslexia) if those learning disabilities related to existing and concurrent developmental disorders. The Developmental Disabilities Act (Public Law 95-605) of 1978 was a detailed explanation that set federal policy and state educational treatment for developmental disorders for many years to come. Newer definitions became less categorical and emphasized functional limitations. Use of the term *impairment* was also advocated and reference to disease was often removed.

### **Contemporary Issues in Defining Developmental Disorders**

Contemporary research and practice for developmental disorders evolved with a more specific focus on components of learning difficulties, or subtypes of learning difficulties. Researchers primarily in the United States separated learning disorders from mental retardation and identified the components of learning disorders in children and adults. Attention focused on memory factors, attentional characteristics, and visual-spatial skills of the learner. In addition, there has been a move toward functional perspectives with particular developmental disorders or disabilities. This approach focuses on more discrete description of skills and adaptive behaviors that individuals need to perform in daily situations. In the past, often the relationship between specific medical diagnostic etiologies and learning disorders did not appear to capture what most individuals needed with respect to their instructional assistance and functioning.

The current definitional trend in developmental disorders also reflects the importance of support-based paradigms in specifying treatments and services

for developmental disorders, as noted by Ruth Luckasson and colleagues. These movements, largely focusing on individuals with mental retardation, do affect the diagnosis and treatment of developmental disorders. Proponents of this support-based orientation of defining disabilities emphasize the opportunity for greater flexibility in diagnosing and classifying such disorders. This shift in thinking is not without controversy. The seemingly simple idea of providing a general diagnosis based upon functional differences related to available supports raises many questions about service provisions, inclusion in instruction, and who has a developmental disorder.

An equally complicating task in defining developmental disorders is related to comorbidity of the developmental problem. In its simplest terms, comorbidity is the condition when two different “disease processes” are present in the same individual. It is relatively common for learning disorders to be associated with attention difficulties, either as a primary diagnosis or as a secondary and concurrent problem. This comorbidity extends to all other emotional and behavioral disorders, and its co-occurrence clearly complicates the diagnostic evaluation procedure and treatment recommendations and potential remediation of the developmental disorder. Progress in the remediation of developmental disorders may often be related to its coexistence with other disorders.

It is also important to ascertain which disorder, if either, is primary. This has implications for all aspects of treatment and types of remediation. Steven Pliszka, Caryn Carlson, and James Swanson have noted multiple diagnostic treatment issues for attention deficit hyperactivity disorder (AD/HD) with comorbid learning disorders. They describe “an overlap between LD and ADHD” for varying learning disorders (reading, spelling, and arithmetic). Furthermore, they report average percentages of 20% to 30% for co-occurrence of AD/HD with learning disorders (LD). More generally, learning disorders coexist with other psychiatric disorders. It has been estimated that 10% to 25% of people (children and adults) with LD as defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV)* have coexisting disorders such as conduct disorder, oppositional defiant disorder, AD/HD, and depressive disorders. Such comorbidity clearly can complicate the diagnosis and treatment of any developmental disorder.

Defining and “diagnosing” a learning disability has reflected and continues to reflect multiple viewpoints,

and this is emphasized in the recently defined Individuals with Disabilities Education Act (IDEA) legislation (Public Law No. 105-17). This information, which appears in the Federal Register for 1997, delineates a definition of “specific learning disability” and outlines criteria for learning disabilities. This is an important definition and details many issues in the definition of learning disability. It indicates that a learning disability must result from a deficit in one or more basic learning areas such as memory, reasoning, organization, and perception; must manifest itself in the form of one or more significant learning difficulties in one or more of seven areas—oral expression, listening comprehension, written expression, basic reading skills, reading comprehension, mathematic calculations, and mathematical reasoning—compared with other children of the same age; must be evidenced by a significant discrepancy between intellectual ability and academic achievement in at least one of these cited seven areas; and must not be caused by mental retardation, hearing or vision impairment, motor impairment, emotional or behavioral disorder, or environmental disadvantage. This is a very general description of learning disabilities, and it encompasses a large number of possible characteristics. It consists of multiple characteristics for inclusion as well as exclusion.

Another contemporary method of defining a learning disability appears in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)*. The *DSM-IV-TR* defines three major types of learning disorders—reading disorder, mathematics disorder, and disorder of written expression—and also a learning disorder not otherwise specified (NOS). No general definitions of learning disability are offered. Also a discrepancy must appear between achievements in the areas of deficit and an individual’s measured intelligence. This ability/achievement discrepancy is probably the most contentious issue in the area of defining learning disabilities at this time.

There are multiple concerns in using the ability/achievement discrepancy as a key factor in defining learning disorders or learning disorder subtypes. Several authors (e.g., Keith Stanovich & Jack Fletcher, David Francis, Byron Rourke, Sally Shaywitz, and Benny Shaywitz) have noted that such discrepancy models do not differentiate subtypes of learning disorders, fail to consider the complex etiologies of learning disorders, obscure differences associated with the identification of gifted children, and may overidentify more intelligent children as learning

disabled. Using the ability/achievement discrepancy as a key proxy for learning disorders appears to be an oversimplification of the complex processes involved in defining and understanding learning disorders.

Contemporary approaches to defining learning disabilities have focused on a neuropsychological assessment. John Obrzut and George Hynd present an especially balanced view of the relevance of neuropsychological data to learning disabilities. A few key points are worth noting. First, general ability testing does not provide much guidance in the specifics of remediation for learning disorders. The hallmark of neuropsychological evaluation is identifying the relationship between certain “brain-related” functions and central nervous system (CNS) locations and functional behavior. Neuropsychological tests provide data concerning perception, attention, memory, motor skill, language, and reasoning. At its best, such assessment relates status factors to actual function. Neuropsychological assessment independently seldom contributes to the amelioration of learning disorders. It can provide documentation of acquired deficits as they relate to learning performance. Rather significantly it is the neuropsychologist’s knowledge of brain and behavior relationships that provides useful information, not the tests or their outcomes per se. Although obvious, this mundane point is central to the diagnostic process in understanding the diagnosis and remediation of learning disorders and information provided by competent neuropsychologists.

## Causes of Developmental Disorders

Hypotheses regarding the causes of learning disorders are well outlined by the team of Daniel Hallahan, James Kauffman, and John Lloyd and by Obrzut and Hynd. There is evidence for neurological differences in the brains of those with dyslexia based upon magnetic resonance imaging (MRI) and positron emission tomography (PET) studies. Evidence suggests functional and structural differences in the CNS of those with reading disorders. Family studies by Christopher Chase, Glenn Rose, and Gordon Sherman have implicated heredity in dyslexia. However, the specifics of genetic transmission are yet to be clarified for dyslexia or specific learning disorders. Teratogens such as alcohol, cigarettes, and illegal drugs have been associated with possible learning disabilities. Perinatal influence such as prematurity and postnatal events such as head injury, lead poisoning, and malnutrition have all been

implicated but only in a general sense. The human genome studies will undoubtedly provide some specifics in the next few years.

### **Subtypes of Developmental Disorders**

For purposes of clarity and specificity, this entry focuses on learning disorders as classified in the *DSM-IV-TR* (2000).

#### ***Learning Disorders***

Learning disorders are diagnosed when the individual's achievement on individually administered, standardized tests in reading, mathematics, or written expression is substantially below that expected for age, schooling, and level of intelligence. Assessment of this last item—level of intelligence—is a requirement for diagnosis of all developmental disorders listed in *DSM-IV-TR*. The learning problems significantly interfere with academic achievements or activities of daily living that require reading, mathematics, or writing skills. A variety of statistical approaches may be used to establish that a discrepancy is significant. "Substantially below" usually refers to a discrepancy of more than 2 standard deviations between achievement and measured IQ. A smaller discrepancy between achievement and IQ is also used, especially in cases when an individual's performance on an IQ test may have been compromised by an associated disorder in cognitive processing, a comorbid mental disorder, a general medical condition, or the individual's ethnic or cultural background. If a sensory deficit is present, the learning difficulties must be in excess of those usually associated with the deficit.

Deciding what is a significant deficit is not easily accomplished. It is unclear what should be considered the "measured IQ point," the total score, or particular subsets, all of which are affected by the underlying learning disorder. This is true for all subtypes. Learning disorders persist into and through adulthood; however, they change in their presentation as functions of time and experience. Residual aspects are difficult to clarify in long-standing learning disabilities especially when impacted by motivational aspects. It is generally estimated that the prevalence of learning disorders ranges from 2% to 10%, depending on the nature of ascertainment and the definitions

applied. Reportedly, 5% of students in public schools in the United States are identified as having a learning disorder.

#### ***Reading Disorder***

Reading disorders are characterized by reading achievement substantially below that expected for age, intelligence, and educational level and that significantly interferes with academic achievement or activities of daily living and in excess of any reading difficulties due to otherwise present sensory deficits. Reading disorder, often called dyslexia, is characterized by oral reading distortions, substitutions, omissions, slow reading, and limited comprehension. Symptoms of reading disorder may occur as early as kindergarten, but it is rarely diagnosed before the beginning of first grade when formal reading instruction begins. In children with high IQ, it may not be diagnosed until after fourth grade, because they may continue to function at or near grade level. A reading disorder follows familial trends, being more prevalent among first-degree relatives of individuals with learning disorders, and it is more prevalent among males. The prevalence of reading disorder in the United States is estimated at 4% of school-age children.

#### ***Mathematics Disorder***

The criteria for mathematics disorder include having mathematical ability substantially below that expected for a person's age, intelligence, and education. This learning disorder must interfere with academic achievement or activities of daily living and supersede mathematical difficulties associated with other present sensory deficits. Such mathematics disorders are estimated to be present in approximately one in every five cases of learning disorder, affecting approximately 1% of school-age children. Multiple skills are impaired in mathematics disorder: linguistic skills—understanding and naming math operations, concepts and decoding written problems, perceptual skills—recognizing numerical signs and symbols, and attentional skills—copying numbers, recalling and completing arithmetic functions, following sequences, and multiple step operations. This disorder reflects a complicated set of deficits in learning skills applied to mathematical concepts and computations. Characteristics of a mathematics disorder may appear as early as

kindergarten; however, it is rarely diagnosed before formal mathematics instruction occurs, usually at the end of first grade. If mathematics disorder affects children with high intelligence, they may continue to function at or near grade level in early grades, resulting in the disorder not becoming apparent until they are in the higher grades.

### ***Disorder of Written Expression***

Disorders of written expression are characterized by writing skills substantially below those expected for an individual's age, intelligence, and education. This learning disorder must interfere with academic achievement or activities of daily writing, and if sensory deficits are present, the difficulties must be in excess of those associated with the current sensory deficit. The difficulties in writing skills are generally apparent in a combination of grammatical or punctuation errors, poor paragraph organization, multiple spelling errors, and excessively poor handwriting, although poor handwriting and spelling errors alone are not necessarily indicative of a disorder of written expression. Poor handwriting and spelling, also called "poor graphomotor skills," is often overdiagnosed as the primary problem. A disorder of written expression rarely occurs separate from other learning disorders, and its exact prevalence is unclear. Characteristics of the disorder of writing expression may appear in first grade, but it is usually more apparent in second grade or after formal writing instruction has occurred. Currently less is known about this disorder.

### ***Learning Disorders Not Otherwise Specified***

This category is for learning disorders that do not "meet criteria" in *DSM-IV-TR* for any particular disorder. When all three features of the subtypes co-occur, this category is used. When the data are equivocal, this is the diagnosis. In some instances, those with other less defined learning disabilities (nonverbal LD) are given this diagnosis.

It is quite clear that the subtype definitions of learning disorders as appearing in *DSM-IV-TR* are not easy to diagnose and are affected by the ability/achievement discrepancy model definition. These subtypes should be used as guidelines for understanding the possible learning disorders and need to be combined with other behavioral, achievement, and assessment characteristics. The criteria as outlined for each disorder in

*DSM-IV-TR* are again guidelines for initial inclusion of these diagnostic categories.

### ***Other Learning Disability Subtypes***

Nonverbal learning disorders (NLD; often referred to as *right-hemisphere learning disorders*) have been identified for some time and are well outlined by Rourke. Currently, the "NLD syndrome" is quite broad and has a variety of characteristics associated with it. According to Sue Thompson, the NLD syndrome reveals itself in impaired abilities to organize the visual-spatial field, adapt to new or novel situations, or accurately read nonverbal signs and cues. Individuals have difficulties in situations requiring speed and adaptability. Nonverbal learning disabilities reportedly involve performance processes often thought of neurologically as originating in the right hemisphere. Much of the initial discovery of NLD syndrome reportedly began in the early 1970s with research involving groups of children with learning disabilities identified by discrepancies between their verbal and performance intelligence abilities. Again such discrepancies are noteworthy but are only a starting point for the diagnostic process.

Thompson lists the following common characteristics of nonverbal learning disorders: "performance IQ significantly lower than verbal IQ, early speech and vocabulary development delayed, remarkable rote memory skills, attention to detail, early reading skills, excellent spelling skills, expresses himself eloquently, lack of coordination, severe balance problems and difficulties with fine motor skills, lack of image and poor visual recall, faulty spatial perceptions, difficulty with spatial relations, lack of ability to comprehend nonverbal communication, difficulties adjusting to transitions and new situations, and significant deficits in social judgment and interaction" (p. 15).

A clear designation of these characteristics is difficult given the current state of research and the wide array of characteristics often reportedly associated with NLD Syndrome. It should, however, be acknowledged that such problems do exist and need to be understood within the context of developmental disorders.

### **Concluding Comment**

Developmental disorders are neither easily diagnosed nor easily remediated with existing instructional techniques. All definitions are guidelines—helpful, but

rarely definitive in their application or discrimination. Assessment and remediation of learning disorders is best accomplished by several individuals. Evaluations completed by a competent neuropsychologist and an educator who are both familiar with developmental processes, measurement methods, CNS functioning, and specific remediation techniques are mandatory. In some instances, the learner's neurological status may require review by a medical professional. Rarely is vision the key reason for a LD. With adults, one is often dealing with comorbid disorders and some long-standing failure and its resultant impact on the learner's self-esteem.

## DISASTERS, IMPACT ON CHILDREN

---

Children are likely involved in disasters wherever they occur. For example, the much-studied 1972 Buffalo Creek flood in West Virginia left 125 dead, 52 of them children. Thousands of children were affected by the tsunami that devastated Southeast Asia in December 2005 and the terrorist attacks in the United States on September 11, 2001. Children are passengers on planes when they crash, are located in buildings when they burn, and live in areas that are flooded. They may even be specifically targeted because of the emotional impact that their victimization has on the community, as evidenced by the 1995 bombing of the Alfred P. Murrah Federal Building in Oklahoma City, which killed 168, 19 of whom were infants and young children.

Although children have always been involved in disasters, the study of disasters and their impact on children is relatively young. Until the early 1980s, it was commonly believed that little, if any, treatment was needed after a traumatic event touched the lives of children. Following groundbreaking work by Robert Pynoos and others, it is now understood that children have significant reactions and that they need mental health services to improve overall outcome. Unfortunately, children's lives are affected regularly by

traumatic events, including child maltreatment, domestic violence, and community violence. When large-scale events occur, such as terrorist attacks or natural disasters like recent hurricanes Katrina and Rita on the Gulf Coast, calamities that directly affect thousands indirectly affect many times that number through the media, and that increases children's awareness of the horrors that can accompany large-scale disasters. Children are considered one of the highest-risk groups for adverse reactions and consequences. However, the mental health needs of children do not seem to be addressed adequately in the preparedness, response, or recovery phases of planning for disasters. This finding is highlighted in a recent report by the National Advisory Committee on Children and Terrorism.

### **Children's Responses**

Children's responses to disaster can be viewed in four categories: cognitive, emotional, physiological, and behavioral. The cognitive reactions include problems with attention and concentration. This difficulty may be coupled with problems with impulse control and decision-making abilities. Problems with memory also may arise. Unfortunately, the professional and the lay communities have been sensitized to interpret the combination of many of these problems as evidencing attention deficit/hyperactivity disorder (AD/HD). Therefore, following disasters or other traumatic events, children may be referred for AD/HD assessment and medication. It is important to evaluate onset of the problems and exposure to trauma in making the diagnosis. (Note: children with AD/HD can be affected by trauma, and their AD/HD will need to be taken into account when assessing their responses.) Another common cognitive reaction is the presence of intrusive thoughts. Children may have images or thoughts of the disaster coming unbidden, often disrupting concentration in school. There may be an increased focus on the event. This will be evident in their repeated discussions of or questions about the disaster. Decreases in self-esteem and ideas of self-blame are two other cognitive reactions seen in children following disaster.

There are many emotional reactions after disaster, with worries, anxieties, and fears related to the event and its aftermath among the most common. Children's worries generally revolve around issues of safety and security for themselves and for others. The sphere of worry expands with a child's age. Very young children may worry about the security of themselves and their

immediate family. As children develop empathy, they may worry about those in their school system, neighborhoods, and community. Older children's and adolescents' worries may include concern about those they may not know who could be touched by the disaster or future similar events. For example, many in this age group may be concerned about children living in Afghanistan and Iraq impacted by the global war on terrorism or about soldiers serving overseas. Anxiety about a reoccurrence of the disaster is extremely common after an event. This anxiety may be exacerbated by trauma reminders. For example, children who experienced Hurricane Katrina may have feelings of worry, fear, and anxiety with thunderstorms and with each new hurricane season, and children living in new and perhaps strange locations may experience loss reminders on a daily basis after the disaster.

Emotional reactions can include a sense of helplessness, guilt, and grief related to the disaster. Children, like adults, may experience emotional numbing, but this appears to be seen more in older than in younger children. Mood swings and irritability, often the hallmark of childhood, may increase after a disaster. Therefore, such reactions should not be viewed merely as a function of the "terrible twos" or the teenage years. Clinicians should look for a change in mood and irritability with friends and family from before to after the disaster.

Physiological effects after disaster can be thought of as bodily reactions. These often include changes in sleep patterns, with problems either falling asleep or staying asleep. Nightmares are common. Unfortunately, when children are not sleeping well, it can impact other areas of their lives, such as learning. Appetite also may be affected by disasters, resulting in either weight gain or weight loss. Many children experience somatic complaints after a disaster, including headaches, stomachaches, fatigue, and flu-like symptoms. Concerned parents may seek medical consultation related to these physical symptoms. It is, therefore, important for mental health professionals and their medical colleagues to work together to assure a comprehensive understanding of common reactions after disaster. Agitation may increase after disaster. For school age children, this response may look like fidgeting at their desks, increasing adults' concerns related to a diagnosis of AD/HD. Children may become hypervigilant after a disaster, with their bodies preparing to respond to any perceived threat. Finally, an increased startle response

may be experienced after a disaster; it can be triggered by loud noises (e.g., sirens, thunder, a car backfiring) or similar unexpected, unpredictable happenings. Once startled, children may have difficulty settling back down and refocusing their attention.

Behavioral effects of disaster are, perhaps, the most observable reactions. Young children may show more separation anxiety. They may be more clingy and whiny than before the disaster. A regression in behaviors also may be noticed: They may have toiletting accidents despite being reliably potty trained, make demands for pacifiers given up long ago, or use baby talk that had been abandoned. Although young children are very proud of self-care skills such as dressing themselves, they may request more help from caregivers and teachers. Older children and adolescents may show a change in social relationships. They may become more irritable and argumentative with family and friends than they were before the disaster. Increased aggression also may be seen. Withdrawal behaviors may be noticed; for example, children of all ages may wish to avoid activities that they once enjoyed, including time with friends, extracurricular activities, or family outings.

Behaviorally, impairments in meeting responsibilities at home and at school may be seen. For example, children may not complete chores as they did prior to the disaster. A brief decline in school performance may occur, such as a failure to complete in-class assignments or homework, a drop in grades, or frustration with learning new material. Although the brief decline is common, clinicians also should be mindful of children who show a significant improvement in their academic performance after a disaster. Generally, these children will become wholly focused on schoolwork to the exclusion of their friends, extracurricular activities, and hobbies. While this focus may seem positive from an academic standpoint (improvement in grades, increased commitment to study and to excel), it should be viewed as problematic if all other activities are avoided or ignored and their importance minimized by the child.

Special attention should be shown to adolescents in the aftermath of a disaster. Adolescents are at risk for experiencing a sense of foreshortened future. Because of this, they may seek new experiences, including those considered high-risk, such as substance use, promiscuity, and reckless driving. Adolescents may become fascinated with death. Depression may be experienced. This combination, coupled with diminished impulse control, poor decision-making, and

withdrawal, places this age group at increased risk for suicide after a disaster.

## Mediating Factors

Children's responses to disaster can be mediated by a number of factors. Perhaps one of the strongest predictors is exposure to the event. The greater the child's exposure, the more likely the adverse reactions will be. Exposure includes being a direct witness to the disaster, including injury and exposure to injury or loss sustained by family members, and perception of the disaster as a threat to the child's life or the lives of family members. Exposure also includes destruction by the disaster of the child's or the child's family's personal property. Loss is a unique category after disaster. Loss includes death of a family member or a pet. When a child experiences the death of a family member due to traumatic circumstances, he or she is at risk for child traumatic grief—the trauma experience may interfere with how grief is processed. With media coverage of disasters being constant and intense, the relationship between media exposure and posttraumatic symptoms has been examined. Results from research studies indicate a strong correlation; however, causation is not clear.

Children of all ages feel more secure in times of crisis when they are with parents or caregivers. The longer children are separated from these important adults in their lives, the greater the risk that the children will have difficulties. Therefore, connecting children with family as soon as possible after a disaster is important. Children also benefit from routine. Disasters disrupt routine, including routines of school, home, extracurricular activities, and community service. Disrupted routine is positively correlated with posttraumatic symptoms (the greater the disruption, the greater the symptoms reported). Routine includes day-to-day activities as well as rules of behavior. Children generally find comfort and stability in order and consistency, so the randomness of disasters or the malicious intent of terrorism may be incomprehensible to them, and they may feel confused and respond with fear and heightened anxiety. It is important to remember that while a return to routine is necessary, it is generally not sufficient to help children in the aftermath of disaster.

When considering which children may be at greatest risk for difficulties after a disaster, it is important to consider which children have previously been identified as being at risk. Preexisting conditions, whether psychiatric or physical, and limitations, such

as mental and educational capacity, condition the child's response to the disaster and postdisaster symptoms. Children who have a history of special services in school or are involved in therapy services should be considered at risk. Similarly, children with a prior history of traumatic events in their lives are also included in this at-risk group. As prior history of the child can help in determining risk, so too can prior history of the family. Factors that can contribute to problems after disaster include how the family was functioning prior to the event. Consider stressors in the family (financial and emotional). Stressors can be both positive and negative. The loss of a job can be stressful, and so too can a move to a new home, especially if this involves a change in school and friends for the child. One of the best predictors of how well children cope after a disaster is how well their parents or caregivers adjust to the event. Adults who are having problems coping with the disaster may not be able to continue fulfilling their appropriate roles as guide, moral compass, and interpreter of the outside world; the child is then unclear about how he or she is expected to behave in a situation. Therefore, when assessing the emotional well-being of children after disaster, it is also important to assess how the family is faring.

Taking a developmental perspective with children in the aftermath of disaster can increase understanding of how children understand, react, and cope with what has happened. The child's developmental level helps predict his or her physical, cognitive, and emotional capacities. For example, preschool children may believe that thinking about something will cause it to happen and so believe that they caused the tornado or the plane crash or the shooting, and the resulting guilt can be overwhelming for them. Young children may not understand "replay," and seeing media coverage of a disaster may give them the impression that the event is happening over and over again, increasing their fears and anxieties. Older children may have a greater appreciation for the unpredictability of disasters and can understand the extent of loss and devastation, leading to concerns about their future, also increasing fears, anxieties, and depressive feelings. Adolescents, because they are closely aligned with friends, view any disruption in being able to see them or talk with them as very distressing. They may, therefore, "overreact" to the closing of their school, the inability to get together with friends, and the possibility of relocating, further contributing to their emotional responses to the disaster. Biological sex, in and

of itself, is relevant only insofar as it relates to the expectations the children learned from their culture; for example, girls may have learned to express emotional reactions, such as crying, and boys may have learned to express cognitive and behavioral reactions, such as behaving stoically or acting out.

Culture, which includes the language, values, beliefs, traditions, and customs that bind people together, provides the context both for interpreting the cause of a disaster and for how to respond to it. Cultures vary in the emphasis they place on the importance of privacy, whether an individual or group perspective is "right," how to comfort others, which emotions are appropriate to express under different conditions, how adults and children are supposed to interact, and whether asking for help is acceptable—and all are involved in predicting a child's reaction to a disaster.

Perhaps the most well-known—certainly the most well-publicized—reaction following a disaster is posttraumatic stress disorder (PTSD). This adult-oriented diagnosis has few reactions that are specific to children. As a result, children may be underrepresented in having this disorder.

For example, an investigation of children's reactions to Hurricane Andrew found PTSD symptoms 44 months after the hurricane in 40% of the children studied, with re-experiencing, hyperarousal, and avoidance or psychic numbing symptoms the most prominent ones. Although PTSD is one disorder that is common after disaster, anxiety disorders, depression, and behavioral problems should also be considered. While a formal diagnosis may be present, it is more likely that symptoms rather than a full diagnosis will exist.

Just as symptoms and pathology may exist, it is also important to focus on strengths. Consider that children have factors that can enhance their ability to bounce back after a disaster. Resilience is this ability to bounce back *quickly* and *effectively* after a crisis. This can be enhanced or taught. While many, if not most, children may be resilient in the face of adversity, this does not mean that interventions are not needed. Children may be resilient in one situation but not in others. While any one of the numerous factors—characteristics of the disaster, dimensions of risk and resiliency, the child's developmental level, and so on—can provide the basis for predicting how a particular child may respond to a particular disaster, the best predictions take into account as many factors as possible.

## Interventions

A full discussion of interventions with children in the aftermath of disaster is beyond the scope of this entry. The appropriateness of individual interventions will depend on how long it has been since the disaster occurred. Consider a mental health triage assessment to determine the need for various levels of intervention. A promising model for this is PsySTART, which helps determine need for as well as allocation of mental health resources following a disaster. In the immediate aftermath of a disaster, Psychological First Aid (PFA) may be useful. There are several models for this, including one sponsored by the American Red Cross and another titled Listen, Protect, and Connect.

Cognitive behavioral treatment approaches to interventions with children after disaster are the most promising for effective outcomes. An intervention for young children after disaster that can be delivered in a group format in various settings is Healing After Trauma Skills. An evidenced-based treatment to be delivered in a school setting to older children who have been exposed to violence or disasters is Cognitive Behavioral Intervention for Trauma in Schools (CBITS). The intervention with the strongest empirical findings for use with children after trauma is Trauma-Focused Cognitive-Behavioral Therapy (TF-CBT). Originally developed for children who have been abused, it has been successful with children who have experienced other traumas, including disasters. If loss is present, TF-CBT has been adapted for this circumstance and it is strongly recommended. A 10-hour free Web-based training in TF-CBT and more information are available at the TF-CBT Web site.

Mental health professionals are instrumental in bringing about overall positive outcomes for children and families after a disaster. To maximize the role of mental health providers, their involvement should begin with all stakeholders in the community in the preparedness phase and continue through the response and recovery phases. Continuous training on this topic is important, as potential events and state-of-the-art responses are always changing.

## DISTANCE EDUCATION/ DISPERSED LEARNING

---

In the current digital age, information is available in greater volumes and with faster access than in any prior time in history. Harnessing this information effectively can be a challenge and an opportunity for counseling educators and students. Technological innovations are changing the educational environment and allowing for a wide array of flexible education

opportunities. Many universities are offering options to traditional face-to-face, on-campus education programs and continuing education opportunities. Distance education can be a cost-effective mode of instructional delivery, accommodating the schedules of a nontraditional student (i.e., older adults with job and family responsibilities). On many college campuses, on-campus students are also opting to enroll in distance education courses and distance delivered course sections to take advantage of flexible scheduling and the opportunity to study when their work and nonschool schedules allow.

### **Universal Design for Learning and Best Teaching Practices**

The underlying premise of distance education is that educational opportunities are available anytime, anywhere, and are designed for everyone (universal design for learning). Underlying the concept of universal design for learning is that a curriculum includes alternatives that make the learning accessible and applicable to students with different backgrounds, learning styles, abilities, and disabilities. When an instructor varies the way a lesson is taught, be it in person or at a distance, more students benefit.

Universal design for learning (UDL) is defined by Bremer and colleagues as an environment and course materials that allow all students, regardless of their abilities and backgrounds, the same access to academic success. The principles of UDL propose adapting instruction to individual student needs through the following:

1. Multiple means of presentation of information to students (e.g., digital text, audio, video, still photos, images, and all with captions as appropriate)
2. Multiple means of expression by students (e.g., writing, speaking, drawing, video-recording, assistive technology)
3. Multiple means of engagement for students (e.g., choice of tools, adjustable levels of challenge, cognitive supports, novel or varied grouping)

Learning increases when different methods, such as slides, videos, music, role-playing, or small group activities are incorporated into the classroom or instructional materials. Flexibility is essential in the learning process. When the design of instruction takes

into consideration the many different types of learning styles, the classroom setting, local events, and the students' personalities, the classroom environment is enhanced, and everyone benefits. UDL builds upon educational traditions and best teaching practices that are very well established in practice and documented in the research literature.

Best teaching practices stand the test of time and are enhanced with technology innovations. The seven principles of best practice, as identified by Chickering and Gamson, are as effective in a distance education environment as they are in a traditional face-to-face classroom. UDL provides a blueprint for creating flexible goals, methods, materials, and assessments that accommodate learner differences.

### **Distance Education Development and Delivery**

Distance education can be developed and offered using a variety of tools and methods. Today's available technology tools for delivering Web-based learning and developing Web-based learning materials can include systems for content and learning management (e.g., Blackboard, WebCT) and designed Web sites (e.g., live, dynamic-interactive). There are many reasons for choosing one learning management system or delivery method over another as there are systems and methods. Blackboard and WebCT are similar and operated by the same organization. They both allow for secure administration of a wide array of online instructional units and materials and for student information management across the PC and Mac hardware platforms. Both products allow for faculty or instructional designers to develop online instructional units using the templates, tools, and components of the learning and content management system. eCollege is a very similar product to Blackboard and WebCT, but the online instructional unit development is often handled by the company using the contracting institution's or faculty's content. The integration with student information systems is similar in Blackboard, WebCT, and eCollege. For a contracted fee with the delivering institutions, most content and learning management systems can manage and deliver HTML, flash, and multimedia instructional materials as well as share content through file exchange tools and manage communication as e-mail redirection portals. There is a wide variety of proprietary learning management systems,

developed within educational institutions, that perform similar functions.

### Principles for Designing Web-Based Learning Materials

Regardless of the tool or vehicle for distributing educational materials, successful Web-based learning materials are based on solid cognitive theory and instructional design theory. Morrison, Ross, and Kemp ask critical questions to frame the instructional design process: What is the purpose of the instruction? What can learners do to demonstrate they understand the material? How can you assess whether the learners have mastered the content? What type of content and performance are specified in the objectives? What is the best way to implement your instructional strategies? How do instructional objectives dictate the selection of evaluation methods? These questions need to be answered taking into consideration how they affect the cognitive domain. Effective learning objectives address information or knowledge, naming, solving, predicting, and other intellectual aspects of the learning process. When these questions have been considered, the real work of developing effective instruction begins.

Materials should be organized in such a way that the learner can easily understand the instructional procedures and policies of the course. The instructor should set clear communication guidelines and expectations. All course information that is delivered orally in a traditional classroom needs to be explicitly listed on the course Web site. Deadlines for the course should be established and published to encourage regular participation from the students and to alleviate procrastination on the part of the student or the instructor. When developing course materials, consider putting the content in modules to break up the information flow into manageable chunks—quite often the course textbook will guide this process, as many textbooks are developed in units, chapters, or sections.

An effective instructional design model encompasses the instructional problem, learner characteristics, a task analysis, development of instructional objectives, sequencing of content, strategies of instruction, message design, instructional development, and evaluation and assessment tools. By taking into account the principles of UDL, counseling educators designing educational materials for in-class, traditional, or distance environments will be preparing

materials that will serve the programs, students, and future clients well.

## DOUCE, LOUISE (1948– )

---

In her autobiographical writings and speeches, Louise Douce described herself as coming of age personally and professionally amidst the “wave of feminism” in academia in the 1970s and early 1980s. She identified feminist values as a core part of her identity and has consistently embodied those values as a clinician, administrator, educator, mentor, scholar, and professional leader. Indeed, her career can be seen as an exemplar of the passionate implementation of the values of empowerment, advocacy, and equality. She once used an image of standing on a bridge to describe significant work that she had done as a counseling psychologist. She indeed has toiled in the

construction of bridges over which the fields of counseling and counseling psychology have moved toward feminism; lesbian, gay, and bisexual (LGB) affirmation; and multiculturalism. She has labored to build bridges that span the integration of science and practice, to lead the way toward effective responses to the changing milieu of professional practice, to connect the counseling professions with a more global perspective, and to link the counseling professions to the future through more effective approaches to professional training.

Douce grew up on a small farm in southern Ohio in what she described as a “small-town Christian family, with missionaries and ministers on both sides.” Her undergraduate education at Ohio State University (OSU) during the Vietnam War era of the late 1960s was a time of great social change and of great personal change for Douce. She described herself as beginning those years believing that the war in Vietnam was justified and ending that era as an ardent feminist who wore a peace sign on her arm at graduation. From 1971 to 1977, she went to graduate school in counseling psychology at the University of Minnesota and did her internship at the Student Counseling Bureau there. She was one of a cadre of feminist women students in counseling who would come to forever change the profession. She has spoken and written about her experiences with sexism in graduate studies, but she has also noted it was an exciting time for young women like her to be feminists and to come out as lesbians. She has discussed the crucial role mentors played in her own development at this time, and she has passed on this legacy of mentoring by becoming a powerful mentor to so many.

Upon completion of her doctoral program in 1977, she became a staff psychologist at the Counseling and Consultation Service at OSU and has remained there for almost 30 years, providing extraordinary service and leadership to one of the most prestigious and respected university counseling centers in the country. Douce became the director for the graduate and predoctoral training program in 1980 and then became the director of the center in 1987. Her work in administering the training program, in providing clinical supervision, and in mentoring have had a significant impact on scores of graduate students and interns. It is safe to say that virtually every counseling center in the United States has been touched by Douce’s work as a trainer and mentor to its staff members. She remained significantly involved in training at OSU even as she became

the director responsible for providing vision and leadership to a staff of almost 20 with a budget of several million dollars. Of particular note for its impact, and for its significance to Douce personally, is that she has been a pioneer in the training of LGB counseling psychologists. In the LGB psychology community, she is a true elder of the tribe and grand-mentor to an entire new generation of LGB psychologists.

Douce’s record of leadership in multiple professional organizations over the last 25 years is far reaching and extensive. Congruent with Douce’s commitment to university counseling centers and professional training, one of the first national organizations for which she assumed a major leadership role was the Association of Counseling Center Training Agencies (ACCTA). She served as secretary from 1981 to 1985 and as president from 1985 to 1988. During this time she provided leadership for the organization in developing policies on intern selection and training, in providing some of the first presentations and workshops on LGB issues, and in establishing an active diversity committee. Around that same time, she also was involved with the American College Personnel Association (ACPA), helping found and lead both the task force on AIDS/HIV and the committee on LGB issues. Douce has also been involved in leadership for the Association of Psychology Postdoctoral and Internship Centers (APPIC), serving on APPIC’s Executive Board from 1988 to 1994, as vice chair from 1989 to 1990 and 1993 to 1994, and as treasurer from 1991 to 1992. During this time, she made a lasting impact on predoctoral internship training in psychology through leadership efforts toward standardizing both APPIC’s internship application and its definition of what constitutes a *practicum hour*.

In the late 1980s Douce’s professional leadership focus began to center on the American Psychological Association (APA). Her strongest involvement has been in APA’s Division 17, the Society for Counseling Psychology. She has served on and/or chaired many committees, task forces, and sections in the division, including those addressing the advancement of women, proficiencies and specialties in counseling psychology, awards, and fellowship status. Douce has been recognized as contributing significantly to the founding of both the society’s section that addresses LGB issues and the section that addresses women’s issues, being a “founding mother” of the latter. She was elected vice president for education and training for 1995–1997 and was elected to the highest office in

counseling psychology as division president for 2002. Though some have identified her as the first LGB president of the division, in her presidential address she identified herself as the first LGB psychologist who became president at a time when open identification would be met with fewer negative consequences. Selecting the globalization of counseling psychology as her presidential focus, she pushed the profession to expand toward a global perspective that would be free from U.S. cultural imperialism. She has represented the division externally in several important ways, including as a representative to APA's governing council beginning in 2006. Currently, she also serves on the APA's Board of Educational Affairs.

Douce has also authored a number of important scholarly publications and presented widely at professional conferences. Her scholarly contributions have focused on issues related to the needs of women, particularly in the career area; HIV/AIDS; LGB affirmative training and practice issues; and professional training and education. There can be no doubt that through her scholarship and the aforementioned professional organization leadership, she has had a significant impact on the education and training of psychologists. In addition, she has participated in a host of major national conferences formulating model training policies, including the national conferences on internship training (1987) and on postdoctoral training (1992), the Joint Council on Professional Education in Psychology (1990–1993), the conference on psychology supply and demand (1997), and the APPIC/BEA competencies conference (2002).

Her commitment and service to counseling and counseling psychology have been recognized through numerous prestigious awards. Douce achieved fellow status with Division 17 of APA in 1995. In 2001, the division awarded her the John D. Black Award for outstanding achievement in the practice of counseling psychology as well as the Woman of the Year award from the society's section on the advancement of women. She received the Distinguished Service Award from the Academy of Counseling Psychology in 2002 and received the Education Advocacy Distinguished Service Award from the APA Board of Educational Affairs in 2005. Her lifetime of service, leadership, and advocacy as a university counseling center psychologist has earned her a number of prestigious lifetime achievement awards from professional organizations that include the Ohio College Personnel Association, ACPA's Commission for

Counseling and Psychological Services, and the American University and College Counseling Center Director's Association.

Colleagues would find little disagreement with Douce's own self-description as bringing "emotional intensity" and a "passionate espousal of values" to her work. There can be no doubt that she has wisely employed that passion and intensity in her work as evidenced by the scope and impact of her work advocating for social justice, developing effective professional education, and advancing the relevance and impact of counseling on society.

## E-COUNSELING

---

One reflection of the explosion of technology in our lives is the increasing use of technology for delivering counseling and psychotherapy as well as other psychoeducational interventions. An individual can use the Internet to locate a counselor, to gain information about psychological conditions and treatments, to obtain counseling, and to share with others in chat rooms or online support groups. In addition to facilitating the exchange of written or audio content, the Internet can provide individuals with face-to-face contact through the use of video technology.

One of the prime advantages of the Internet in delivering mental health services is that clients who have difficulty obtaining face-to-face contact because of health conditions, remote locations, or other barriers can obtain services that would otherwise not have been available. Examples would be clients living in remote areas where a long drive to obtain clinical services cannot be regularly accomplished; clients whose physical health conditions limit their mobility; clients who live in areas where psychologists, counselors, or other mental health care providers are sparsely distributed; and clients whose psychological condition makes them less likely to seek face-to-face delivery of services but more likely to use the less personal nature of the Internet for chat rooms or support groups. Another advantage of the Internet is that it can be used as an adjunct to regular treatment. An example is that of pain patients who can log on to a Web site where they can enter data about their pain levels, obtain materials about coping strategies they

have already been taught, post questions to therapists or other patients, and obtain support between regular treatment sessions.

### **Ethical and Legal Issues**

However, using technology as the sole or adjunctive means of delivering psychological services poses significant ethical and legal issues. The APA ethical code does not have a separate section on electronically transmitted services. Rather, codes incorporate online treatment as deemed necessary within appropriate categories. For example, the standard on informed consent says that psychologists delivering online treatment must warn clients of the limits of confidentiality inherent in this type of communication.

Mallen, Vogel, and Rochlen outlined several areas where the ethical code may be tested in online formats. One such area is the duty to warn: to protect clients if they pose a danger to themselves or to warn others if the client poses a danger to them. If services are being provided at a distance, it may be difficult to meet this standard. Another example is confidentiality: By their very nature, online interactions are vulnerable to hacking or being penetrated by a third party. If an online exchange is saved by either the client or counselor, the data are equally vulnerable to breaches of confidentiality. Encryption is a possible security step but cannot be relied upon to provide complete protection.

A different type of confidentiality issue is the protection of tests and assessments. Psychologists are ethically obligated to maintain the security of psychological tests and assessment methods. However, if

such assessments or tests are transmitted to clients, their security cannot be maintained. In a research setting, when tests are used in online surveys, similar concerns apply.

Legally, psychologists and counselors practice under a license issued by their state. Online treatment tests this limit of practice, because psychologists and counselors may be treating clients in their own state, an adjoining state, a different state, or a completely different country. Mobility issues for psychologists from state to state are being addressed, as are mobility issues for psychologists from country to country. But the advances of online technology have surpassed any advances in mobility in regard to licensure and credentialing.

### Training Issues

In spite of the advances in technology that faculty and students use on a daily basis (e.g., to conduct literature searches via online databases or to download research articles), training in counseling and psychotherapy still adheres primarily to a supposition that counselors will be treating their clients in the traditional face-to-face, office-based, 45- or 50-minute session. Clearly, not all counselors or psychologists are interested in delivering online services, and not all faculty are able to prepare students to do so in future careers. But several training issues apply.

First, at a minimum, students should be competent in computer-aided communication. This competence would extend to chat rooms, encryption, and various hardware and software programs.

Perhaps more important is communication via text. Counselors are skilled at empathy: picking up on client's verbal and nonverbal cues and recognizing the affect behind them. This skill is much more demanding with text communication. Counselors may need to learn to ask questions in a different manner than they do in person and to convey their responses much more directly than they might usually do in conversation.

Ethical and legal issues that may arise in online counseling must be considered during graduate education in the same way that ethical and legal issues arising from in-person treatment are considered. While practica may not provide opportunities to identify these issues, faculty teaching courses in ethics and issues can include a section on online treatment and might profitably include a panel of local practitioners

who deliver online services and have wrestled with relevant ethical issues.

## EMPIRICALLY BASED PROFESSIONAL PRACTICE

---

Professional practice based on reliable and valid empirical findings of effectiveness—empirically based professional practice (EBPP)—has increasingly influenced the work of mental health practitioners over the past two decades. The appeal of EBPP is based on the conviction that using evidence-based assessments and treatments in preference to those

without empirical support makes sense, because EBPPs have been compared systematically to alternative treatments by appropriate and powerful methods and, for that reason, should provide practitioners assurance of superior efficacy.

Many believe that medical practice has long been heavily influenced by the most current available scientific data. However, that assumption may not be valid. The roots of evidence-based medical practice (EBMP) are shorter than many may have thought: They are usually traced to a statement published in the *Journal of the American Medical Association* by a group of physicians led by a Canadian internist that advocated evidence-based medical practice over medicine as an art. The article led to a debate about power, ethics, and responsibility in medicine that appears to have radically altered healthcare practices. Although this change has led physicians away from intuition (the art in medicine) toward empirical data (the science in medicine), divisions among physicians over the value of intuition continue. Some have said that the EBMP position is unequivocal: There are reliable, validated data, and then there are data that aren't reliable and validated, and the difference between the two is what is important.

Parallels between the nature of and reactions to evidence-based medical practice and evidence-based mental health practice are clear. What advocates for evidence-based treatments in psychology, psychiatry, and social work hear from their critics is strikingly similar to what those who support evidence-based medical practices hear from their critics, as are the efforts of advocates for evidence-based mental health practice and advocates for evidence-based medicine to counter those criticisms with data.

### **History of Concern for Evidence of Efficacy in Professional Psychology**

The issue of the evidence base of clinical practice in psychology has a lengthy and important history that dates back more than 60 years to the period of explosive growth of professional psychology during and after World War II that transformed it from a small, primarily academic discipline to one of the core mental health professions. As long ago as 1942, social psychologist Theodore Sarbin predicted, on the basis of some of his own data, that actuarial prediction methods ("science") would ultimately be able to outperform humans ("art") along a variety of judgment dimensions. In 1954, Paul Meehl, who was to become

one of the towering figures in clinical psychology over the next several decades, published a book that summarized his data confirming the consistent superiority of statistical prediction ("science") over clinical prediction ("art"). Although advocates for art rather than science in clinical and counseling psychology since then have been heard from, support from behavioral scientists for the positions Sarbin and Meehl took so long ago on this issue has been strong and consistent.

Notwithstanding opposition to evidence-based practice by some mental health professionals, increasing efforts are being expended to require mental health practitioners to follow practice guidelines, and practice guidelines are becoming more prescriptive. Managed care organizations, third-party reimbursers, and state and federal agencies have come increasingly to expect psychologists, psychiatrists, and social workers whenever possible to employ practices with empirical support. As a consequence, many psychology and social work students and psychiatric residents receive training that emphasizes these practices as mandated by their professions. Practice guidelines incorporating evidence-based treatments have been put forth by the American Psychological Association and the American Psychiatric Association as well as by the U.S. Department of Veterans Affairs and the U.S. Agency for Health Care Policy and Research. And more and more patients have come to expect their therapists to know and use empirically supported treatments whenever possible.

Despite these developments, disagreement continues to divide mental health professionals on the strength and legitimacy of the evidence base that underlies evidence-based practices. Three pressing unresolved issues underlie this controversy; they are briefly considered below. Resolution of these issues appears to be essential to the future of evidence-based practices. If some or all of them can finally be resolved, agreement by most mental health professionals on the worth of evidence-based practices would likely be assured. By the same token, if few or none can be settled, the momentum toward evidence-based practices might well slow.

### **Issue #1: Efficacy Model Versus Effectiveness Model**

Which of two psychotherapy outcome research models—the efficacy model or the effectiveness model—best captures the most crucial differences among therapy techniques and procedures and, hence, can be relied on to provide the most accurate picture

of therapy outcomes? The *efficacy model* describes most carefully controlled, time-limited psychotherapy outcome research, much of it involving random assignment of patients to treatments, done largely by psychotherapy researchers in laboratory or other controlled settings, using therapists intensively trained to provide the experimental treatment and psychotherapy patients carefully selected diagnostically to receive it. The *effectiveness model* describes psychotherapy research done in real-world clinical settings, utilizing clinicians in their usual treatment settings doing the kind of psychotherapy they customarily do with the patients who customarily come to see them in those settings.

Most of the research that has led to identification of evidence-based treatments to this time has been done according to the efficacy model. As a result, critics of the evidence underlying evidence-based treatments have claimed that efficacy studies do not reflect therapy outcomes “in the real world.” While supporters of the efficacy model have mounted a vigorous defense of the treatment model, the question of which of the two models provides the most valid picture of psychotherapy outcomes remains unresolved. Until it is, the evidence base of evidence-based treatments will remain suspect.

The efficacy model and the effectiveness model represent quite different approaches to studying behavior change. Because neither model by itself appears to capture the entirety of what makes a treatment effective, clinical researchers have begun to try to integrate the two approaches in the design of psychotherapy research in the effort to gather the most broadly based empirical support for the treatments being evaluated and resolve the controversy.

## Issue #2: Common Factors Versus Treatment Factors

The controversy over Issue #1—the relative validity of efficacy versus effectiveness studies in assessing treatment outcomes—came to a head with the publication of practice guidelines by the American Psychiatric Association and the Division of Clinical Psychology of the American Psychological Association. However, the appearance of these guidelines also led critics of evidence-based practices to step up the amplitude of a related continuing controversy: This issue has to do with whether differences in psychotherapy outcomes are more strongly associated with specific types or schools of psychotherapy (as advocates for empirically supported treatments affirm) or with therapist, patient,

and therapy process variables common to all psychological treatments.

*Treatment factors* refer to the array of therapeutic behaviors and techniques a therapist is taught and must learn as he or she acquires the skills appropriate to the practice of a specific intervention. By contrast, *common factors* refer to factors influencing outcomes presumed to be independent of the specific treatment employed, including patient attributes like age, gender, and personality; therapist attributes like interpersonal and social skills; and the nature of the relationship between therapist and patient.

Therapist variables thought to impact on therapy outcomes regardless of the kind of therapy techniques the therapist uses range from the therapist’s demographic characteristics and sociocultural background to subjective factors like values, attitudes, and beliefs. Prominent psychologist Larry Beutler believes that therapist variables reflecting behaviors specific to the therapeutic relationship, including the therapist’s professional background, style, and choice of interventions, may exert the most powerful effects on therapy outcomes. After an extensive review of outcome research data, Michael Lambert and Allen Bergin concluded that about 30% of psychotherapy outcome variance is attributable to therapist variables, prominently including therapist empathy, warmth, and acceptance of the patient.

In contrast to the voluminous data on the impact of therapist variables on therapy outcomes, patient variables have failed to demonstrate a robust relationship to outcome variables. In a well-known National Institute of Mental Health Treatment of Depression Collaborative Research Project (NIMH-TDCRP) comparative study of treatments for depression, for example, no single patient variable correlated significantly with outcome. More recently, the National Institute on Alcohol Abuse and Alcoholism’s Project MATCH failed to identify relationships between patient-treatment matches and outcomes of treatment for alcohol abuse and dependence.

Therapeutic process variables—factors influencing therapists’ reactions to patients’ behavior and attitudes and vice versa—have also been claimed to affect therapy outcomes. To this end, David Orlinsky and Kenneth Howard concluded that process variables, which they believed include the strength of the therapeutic bond, the skillfulness with which interventions are undertaken, and the duration of the treatment relationship, all impact positively on outcomes. Others have also stressed the central role of the therapeutic alliance in determining outcomes. Most

recently, Louis Castonguay and his colleagues reviewed the extensive data on relationship factors in the treatment of dysphoric disorders, concluding that these factors positively influenced treatment outcomes. Nonetheless, critics of process research have continued to emphasize the difficulties associated with the reliable collection of process data.

### Issue #3: The Dodo Bird Effect

The dodo bird effect, so designated by Saul Rosenzweig in a prescient 1936 article on common factors in diverse psychotherapies, is named after the well-known race in Lewis Carroll's *Alice in Wonderland*. At the conclusion of that contest, the dodo bird declares that since the racers, including Alice, had failed to keep to the racecourse, it was impossible to know who had won and, so, "Everyone has won and all must have prizes." Thus, the dodo bird effect in psychotherapy research refers to findings that indicate that there are few or no meaningful differences among psychotherapies in effectiveness and that, accordingly, outcomes of therapy don't really depend on the kind of therapy patients.

Acknowledging their debt to Rosenzweig for his initial reference to the dodo bird, Luborsky, Singer, and Luborsky wrote a review chapter in the 1970s in an edited volume on psychotherapy evaluation, "Comparative studies of psychotherapies: Is it true that 'everyone has won and all must have prizes'?" Luborsky and his colleagues compared outcomes from group and individual psychotherapy, time-limited and open-ended psychotherapy, and client-centered and psychodynamic therapy, concluding that most studies of psychotherapy have found insignificant differences in the effectiveness of different psychotherapies.

More recently, the dodo bird effect has been taken to refer to efficacy comparisons among psychotherapies by means of meta-analyses that have failed to find differences in efficacy. By now, a number of psychotherapy researchers besides Luborsky and his colleagues have adopted the same position—that most psychotherapies are effective in inducing behavior change, but that they do not differ in efficacy. A number of behavioral researchers, however, have vigorously disputed this position. They point to data from a number of randomized clinical trials that strongly suggest that some psychosocial treatments—most of them behavioral or cognitive behavioral—do appear to yield significantly better outcomes than do other psychotherapies. In so doing, they also cite data finding substantial problems with meta-analysis as a means of

comparing the differential efficacy of psychotherapies. As noted above, the drafters of practice guidelines by the American Psychiatric Association, the American Psychological Association, and the Mental Health and Behavioral Science Service of the Veterans Administration, among others, have taken similar positions in recommending some treatments over other treatments on the basis of outcome studies.

### Present Situation

The well-known complexity of the psychotherapy process—in particular, the range of variables in the relationship between patient and therapist that are capable of influencing therapy outcomes—has led advocates for and critics of evidence-based treatments to the present situation. On the one hand, advocates point to voluminous data attesting (a) to the power of efficacy studies to differentiate among therapies in outcome, (b) to the association of specific kinds of treatment, most often cognitive-behavioral, with positive outcomes, and (c) to the failure of "art" through history in its struggle with science for primacy. On the other hand, critics have no problem citing research in each instance that supports their view that these questions cannot be resolved nearly as simply and expeditiously as the advocates would like.

While the most attractive solution to this conundrum is to suggest that partisans on each side of this issue tone down their rhetoric until enough data have been gathered to resolve these questions, that solution is unlikely to satisfy either side.

## ETHICAL CODES

---

Ethical issues are often complicated and multifaceted and can be challenging for counselors if they attempt to create simple solutions when dealing with difficult

issues. Many ethical issues are gray, not black and white, and it is common for biases and personal values, beliefs, and morality to enter the decision-making process. As a result, ethical codes are designed to provide guidelines and general standards for counselors to deal with a variety of ethical issues and situations.

Ethical issues are regulated by laws and ethical codes. However, most people do not understand the inherent difference between the two. *Law* is a set of rules established by governments, and it defines the minimum standards that people in society tolerate. *Ethics*, on the other hand, is a set of ideal standards established by a profession as moral principles that members should adopt as a guide for conduct. As a result, ethical codes are generally broad instead of precise and specific. In addition, ethical codes are edited frequently due to the emergence of new issues or the clarification of old ones. For instance, more clients seek counseling using technology than was the case decades ago; thus, there is a need to address potential issues that might occur when integrating technology into counseling. No clear-cut lines separate ethics and laws; hence, counselors often make ethical decisions based on their maturity, philosophy, experience, and knowledge.

### Ethical Codes in the Counseling Profession

The first American Counseling Association (ACA) ethics code was established in 1961, and revisions were made during 1974, 1981, 1988, 1995, and 2005. The first version of the Code of Ethics for Marriage Counselors was developed in 1962, and the eighth revision was published in 1991. The ACA code of ethics is the most well known and practiced by counselors.

### Moral Principles in Making Ethical Decisions

The primary reason for counselors to follow an ethical code is to protect clients' welfare, and the following six basic moral principles are priority guidelines designed to help them make most appropriate decisions. *Autonomy* refers to counselors allowing clients to make their own decisions, with the therapist respecting any choices made. *Nonmaleficence* means doing no harm, and counselors should strive at all times to avoid hurting clients, even when intentions are worthy. *Beneficence* means counselors doing what

is good for clients. *Justice* means counselors providing equal treatment to all individuals, regardless of their background, age, gender, religion, ethnicity, etc. *Fidelity* means counselors making honest promises and honoring their commitments to their clients. *Veracity* refers to being truthful.

Ethical codes are not blueprints, and therapists will likely be challenged during an ethics application process. It is essential for mental health professionals to understand that potential problems exist and are encountered when counseling ethically. For instance, (a) some issues cannot be handled by simply checking ethical codes, (b) some codes are opaque and difficult to follow, (c) at times, conflict exists within ethical codes as well as among the codes of other organizations, (d) ethical codes are more likely to be reactive than proactive, and (e) conflicts may arise between institutional policies and practices.

### ACA Code of Ethics

The ACA code of ethics consists of seven sections: Section A: the counseling relationship; Section B: confidentiality, privileged communication, and privacy; Section C: professional responsibility; Section D: relationships with other professionals; Section E: evaluation, assessment, and interpretation; Section F: supervision, training, and teaching; Section G: research and publication; and Section H: resolving ethical issues.

#### Section A

This section addresses ethical issues involved within the counseling relationship. The first issue concerns clients' welfare. A mental health counselor's primary responsibility is to ensure his or her clients' dignity and welfare; counselors may achieve this goal by following the guidelines in this section. Counselors should keep sufficient and timely records, and these should reflect clients' progress as well as different services provided by the counselor.

The second issue concerns informed consent. Clients have the right to detailed information regarding counseling services and the counselor before making a decision to continue with counseling. Counselors have the responsibility to review informed consent both verbally and in writing with the client concerning his or her responsibilities and rights. Therapists explain the type(s) of counseling services the client will receive as well as the counseling purpose, goals, techniques,

procedures, limitations, potential risks, and benefits. Counselors should provide professional information about themselves, such as their qualifications, credentials, experiences, etc. When dealing with clients unable to give consent, counselors need to obtain assent from an appropriate collateral (e.g., parent, guardian).

The third issue deals with the professional relationships that a client may have with other mental health professionals. Under such circumstances, a counselor requests a release from the client to inform those other professionals about the counselor's work with the client. The counselor also tries to establish positive professional relationships with the other health professionals working with the client. The fourth issue addresses how counselors can avoid harm by not imposing their values on the client. Counselors respect their clients and are aware of their own personal values while avoiding the temptation to inculcate them into their clients.

The fifth issue concerns counselors' roles and relationship with their clients. Any sexual or romantic relationship is strictly prohibited. When counselors are involved with their former clients sexually or romantically, a document must prove their last professional contact was at least five years earlier. In addition, other documents must show that their new relationship will not psychologically harm the former client. When counselors engage in nonprofessional relationships with clients, the counselor must provide documentation to prove that the clients benefit from such a relationship. When the counselor's professional role changes, he or she needs to obtain new consent from the client.

The sixth issue discusses counselors' and clients' roles and relationships at different levels, such as individual, group, institutional, or societal levels. When roles change, counselors must examine any potential barriers that might restrain clients' growth. The seventh issue concerns counselors providing counseling services to multiple clients. Under such circumstances, counselors clarify their relationship with each specific client. The eighth issue centers on group work. It is essential for counselors to select group members who have goals that are compatible with those of other group members. In addition, counselors need to protect group members from physical, emotional, and psychological damage.

The ninth issue discusses potential ethical issues when dealing with terminally ill clients. Counselors need to provide high-quality end-of-life care to clients while enabling them to engage in decision

making regarding their end-of-life care. Meanwhile, counselors have the responsibility to provide appropriate referral information while ensuring that clients receive adequate assistance. In addition, counselors must recognize their personal, moral, and competence issues when working with terminally ill clients. If terminally ill clients decide to accelerate their own demise, therapists need to follow applicable state law and decide whether to break confidentiality. However, before making such a decision, counselors seek consultation or supervision from appropriate professional parties.

The tenth issue is about fees and bartering. While establishing fees, counselors need to take clients' financial status into consideration. If the established fee structure is inappropriate for a client, the counselor has the responsibility to assist the client in finding comparable services at an acceptable cost. When clients fail to pay their fees, clients need an opportunity to make payment before counselors use collection agencies. If clients suggest bartering, and it is acceptable among professionals in their community, counselors may accept it. When determining whether or not to accept gifts from clients, counselors consider how it might affect the therapeutic relationship.

The eleventh issue is about termination and referral of counseling services. Counselors never abandon clients under any circumstances, such as illness, vacation, and so on. In fact, counselors need to arrange for clients to continue treatment if the counselor is unavailable to continue providing counseling services. If the client rejects the referral, the counselor needs to terminate the counseling service. In addition, counselors should terminate the therapeutic relationship when the client will not benefit from further services, the client fails to pay fees, or there is potential harm for the client. After termination, counselors need to make appropriate referrals for the client.

The twelfth issue concerns potential ethical issues when integrating technology into counseling. It is the counselor's responsibility to inform clients regarding any benefits and limitations while implementing technology into counseling services. Counselors need to be aware of their clients' intellectual and emotional capability as well as the appropriateness of the type of technology they plan to use in the counseling session. When counselors realize long-distance counseling service is not appropriate, they provide face-to-face counseling sessions to their clients. Counselors are responsible to ensure the technology implementation

does not violate the law. Counselors also receive informed consent from the client, which must address any potential technological issues concerning the counseling sessions. In addition, when counselors maintain sites on the Web, they regularly update the content and stay current with the activity on their sites. They also need to have other modes of communication with the clients if the technology fails.

## ***Section B***

Section B addresses ethical issues regarding confidentiality, privileged communication, and privacy. The first issue concerns counselors respecting the rights of their clients. When working with clients whose ethnic or cultural background is different from theirs, counselors are aware of and sensitive to their clients' culture, recognizing that it might have impact on confidentiality and privacy issues. Counselors respect clients' privacy and seek personal information from the client only when the relationship can gain from acquiring it. Counselors may share a client's information with others only when they have the client's consent and a legal or ethical justification for this action. In addition, counselors must inform clients regarding the limitations of confidentiality, identifying specific situations when confidentiality must be breached.

The second and third issues center on how counselors disclose clients' personal information. Counselors disclose only when the client is in danger of hurting him- or herself or in danger of injury from someone else. When counselors are under a court order to release clients' personal information, it is important for them to obtain informed consent from the client and to disclose as little information as possible. Counselors have the responsibility to ensure that clients' private information is not revealed to other professional parties, such as employees. If clients are involved in treatment, they should be informed that their personal information might be shared with other professionals as well as the purpose for doing so. Counselors discuss clients' information only when they are sure that privacy will be maintained.

The fourth issue is about potential ethical issues regarding group and family counseling. Because more than one client is involved in such a counseling relationship, it is essential that counselors clearly explain the importance of confidentiality to each client. The fifth

issue is about clients' capacity to give informed consent. When dealing with incapable clients (minors or adults), counselors need to protect clients' confidentiality based on specific laws and/or ethical codes. In addition, when working with these clients, counselors obtain permission from an appropriate party regarding the release of confidential information.

The sixth issue concerns how counselors handle clients' records. It is essential for counselors to keep clients' records in a secure place where only authorized individuals have access. If counselors need to record or observe counseling sessions, they must obtain clients' permission beforehand. The seventh issue is about research and training. When counselors conduct research, they must receive institutional approval first. In addition, counselors need to be cautious about disclosing any information that might lead to the identification of certain research participants. The eighth issue concerns consultation within the counseling relationship. When counselors consult with others, they have the obligation to protect clients and not disclose information that might lead to identification of certain clients.

### **Section C**

This section is about counselors' professional responsibility. The first issue concerns knowledge of standards. It is a counselor's responsibility to read and comprehend the ethical codes and standards of the profession. The second issue involves professional competence. Counselors should practice counseling based only on their education, training, and professional credentials as well as professional experience. If counselors practice in a specialty area different from the one in which they have been educated or trained, they must take steps to ensure their competence in order to protect potential clients from harm. They should continually monitor and improve their professional skills. When counselors have questions regarding their ethical obligations, they should seek consultation from other counselors. In addition, counselors need to take steps, such as receiving continuing education, to maintain their competence level.

The third issue addresses how counselors advertise for and solicit clients. When advertising, counselors must provide accurate information when identifying their credentials in order to not mislead clients. In addition, when counselors develop professionally related products, they should not use a counseling,

supervising, or training relationship to promote their goods. The fourth issue centers on counselors' professional qualifications. Counselors must truthfully represent their qualifications and accurately describe their professional training, and they may refer only to licenses and certifications that are current and in good standing. Counselors are responsible to state their educational degree as well as the accreditation of their institution at the time their degree was completed. Counselors must distinguish their current from their former association memberships. The fifth issue states that counselors should not discriminate against their clients, supervisees, students, or others based on race, age, culture, religion, and so on.

The sixth and seventh issues discuss counselors' responsibilities to the public and to other professionals. Counselors should not engage in sexual harassment and should strive for accuracy and objectivity when asked to provide professional reports or judgments to third parties.

### **Section D**

This section primarily discusses counselors' relationships with other professionals. The first issue centers on counselors' relationship with their colleagues, employees, and employers. Counselors need to respect others providing counseling approaches different from their own, and they should strengthen their relationships with other colleagues in order to provide the best services for their clients. When counselors are employed in an agency or institution, the implication is that the mental health professionals working there agree with their employers' general policies and principles. However, when counselors identify inappropriate policies or practices of their employers, they take steps for making constructive changes. When such policies have damaged the effectiveness of counseling, they need to refer clients to another appropriate agency.

The second issue is about consultation. When counselors are requested to provide consultation services, they need to ensure their competency as consultants. They are also obligated to review rights and responsibilities for both themselves and consultees. In addition, they seek understanding with their consultees regarding problem definition, goals for consultation, and predicted intervention results. They are also responsible for communicating with consultees regarding related consultation issues, such as the

purpose of the consultation service, costs, and potential risks and benefits.

### **Section E**

This section is concerned with how counselors use instruments to evaluate clients and the accuracy of any interpretation of results. There are 13 issues in this section. The first issue is general information regarding assessment. It is a counselor's responsibility to select reliable and valid instrument(s) to measure a client's personality, ability, interest, intelligence, or performance. In addition, counselors must know how to interpret the assessment results. Their interpretations should be available to clients when requested.

The second issue addresses counselors' competence using and interpreting assessment instruments. Counselors may use only assessments that they have received adequate training to and are thus competent to administer. In addition, if counselors serve as supervisors, they need to hold the same standards to ensure their supervisees' assessment competence. Counselors are responsible for appropriate scoring and the interpretation of instruments used meeting the needs of their clients. Counselors are especially responsible for any decisions made that are based on clients' assessment results. They must have a thorough understanding of the psychometric properties of any instrument used, such as validation criteria, assessment research, and assessment guidelines for development and use.

The third issue discusses informed consent. Counselors should explain to their clients the purpose and nature of the instrument prior to assessment. Meanwhile, counselors need to be aware of their clients' culture and level of understanding of the assessment results as well as the potential impact such information might have on the clients. The fourth issue is about releasing assessment data to other qualified professionals. Counselors may only release clients' data to other qualified professionals after obtaining the consent of the client or the client's legal representative. The fifth issue discusses how counselors should carefully select instrument(s) and appropriate assessment techniques for a mental disorder diagnosis. In addition, when diagnosing diverse clients, counselors need to take into consideration a client's culture. Counselors may abstain from reporting a diagnosis that they believe would bring harm to a client.

The sixth issue addresses how counselors should appropriately select an instrument for assessment purposes. Certain criteria, such as validity, reliability, psychometric limitations, and appropriateness of a particular instrument need to be carefully investigated before selecting the instrument. In addition, counselors need to be cautious when selecting instruments for culturally diverse clients and avoid using instruments that appear to have a lack of psychometric properties for the population the client represents. The seventh issue concerns the administration conditions. If, in an effort to accommodate a client's special needs, a counselor administers an instrument under nonstandardized condition(s), these conditions must be reported in the interpretation. In addition, counselors must understand that the results might be invalid.

The eighth issue regards multicultural issues in assessment. Counselors should be familiar with the effect of a client's age, gender, race, religion, language, and other cultural components. The ninth issue concerns scoring and interpreting the assessment results. Counselors should recognize reservations that exist regarding validity and reliability of the instrument. The tenth issue addresses the need for counselors to maintain security of tests and assessment. Counselors may not reproduce or modify a published assessment prior to obtaining permission from the publisher. The eleventh issue states the need for counselors not to use outdated assessments. The twelfth issue addresses counselors' responsibility to select assessment methodologies based on scientific procedures, relevant standards, and professional knowledge. The thirteenth issue discusses forensic evaluation and evaluation for legal proceedings. When counselors provide forensic evaluations, their opinions must be objective and supported by data gathered during the evaluation.

### **Section F**

This section discusses supervision, training, and teaching issues. The first issue regards clients' welfare with supervision. When counselors serve as supervisors, they are responsible for their supervisee's understanding and following of ethical codes. In addition, supervisees must explain to their clients who will have access to the clients' records. The second issue concerns supervisors' competence level. Before supervisors provide any clinical supervision, they must receive adequate supervision training. The third issue is about supervisory relationships. Supervisors

should explain the professional supervisory relationship to their supervisees and avoid any kind of non-professional relationship with current supervisees. Supervisors are banned from developing any sexual or romantic relationship with current supervisees.

The fourth issue states supervisors' responsibilities. Supervisors ensure their supervisees' awareness of professional and ethical standards and encourage them to follow those standards. In addition, if either the supervisor or the supervisee intends to terminate the supervisory relationship, he or she must give adequate notice to the other before doing so. The fifth issue is about supervision, evaluation, and endorsement. It is essential for supervisors to have periodic formal evaluations with their supervisees and to provide feedback. Supervisors need to be aware of supervisees' limitations and help them understand options. Supervisors also support supervisees for certification, licensure, or employment.

The sixth issue discusses counselors' responsibilities as counselor educators. Counselor educators demonstrate that they are skilled teachers and practitioners. They are knowledgeable about legal and ethical issues, and they help their students become aware of their responsibilities. In addition, counselor educators integrate multicultural materials into classes and workshops for the development of professional counselors. When teaching counseling techniques that lack sufficient and solid empirical research data to prove their effectiveness, counselor educators should explain to students about the lack of research support. Moreover, they should explain any potential risks that might arise when applying these techniques to practice.

The seventh issue refers to students' welfare. Counselor educators should clarify to students what the expectations are for the training program. The program should provide the type of skills and knowledge students need for completing the program. The program needs to provide employment data on their graduates. The eighth issue discusses counseling students' responsibilities. They should follow the ACA codes, sharing the same obligations to clients as professional counselors. The ninth issue is about evaluation and remediation of students. Counselor educators must provide ongoing feedback to their students throughout the training program. In addition, if students request counseling, counselor educators should make appropriate referrals for them.

The tenth issue addresses roles and relationships between students and counselor educators. Any sexual

or romantic relationship between counselor educators and current students is forbidden. Counselor educators must avoid any nonprofessional relationship with students that might potentially harm the student. In addition, counselor educators may not accept any form of service or fee from sites, students, or supervisees. Counselor educators may not provide long-term counseling services to current students.

### ***Section C***

This section concerns potential issues when counselors conduct research. The first issue addresses counselors' responsibilities as researchers. When counselors conduct research, they must report their research following ethical principles and federal and state laws as well as the regulations of the host institution. When counselors recruit humans as research participants, they must avoid harming these participants psychologically, emotionally, or physically. In addition, if counselors do not have access to an institutional review board (IRB), they need to consult with people familiar with IRB regulations.

The second issue addresses the rights of research participants. Before participating in any research, subjects must provide consent. In the consent form, researchers clearly state the purpose of the research, explain procedures in detail, and describe any limitations of confidentiality. In addition, researchers must indicate that participation in the study is voluntary and that participants may withdraw at any point during the process without penalty. If students or supervisees are involved as subjects in research, researchers must inform them that any decision they make concerning participation will not affect their supervisory relationships or the evaluation of their academic performance. In addition, researchers must inform their research project sponsors or institutions about their research results. After a reasonable period of time, researchers must destroy their research data.

The third issue concerns counselors' relationship with the participants in their research. Counselors are not allowed to develop any nonprofessional relationship, such as a sexual or romantic relationship, with their participants. However, if counselors feel any non-professional interaction between them and their participants might benefit their research outcome, their interaction should be documented. In addition, counselors need to acquire consent from their participants prior to engaging in the interaction. The fourth issue

addresses reporting accurate research results. Counselors should not report falsified research results and mislead readers. The fifth issue discusses publication issues. Counselors should not plagiarize others' work and must always recognize others' contributions.

## Section H

The primary issues in this section are centered on resolving ethical issues. Counselors should be knowledgeable regarding the ACA code of ethics and codes of other licensure organizations. Their professional behavior must follow legal and ethical standards. When counselors face ethical dilemmas, they should consult with colleagues or supervisors. If the conflict exists between ethics and law or other regulations, counselors should take appropriate steps to resolve the conflict. When counselors suspect their colleagues are acting in an unethical manner, they take appropriate action. If a violation has harmed an individual or organization and has not been appropriately resolved, counselors should take further action to address the issues.

## ETHICAL DECISION MAKING

---

Ethics as a construct has its intellectual roots in the discipline of philosophy. The term *philosophy* is a translation of the combination of the Greek words *philos*, meaning love, and *sophia*, meaning wisdom. Hence, the study of ethics has as its foundation a *love for wisdom*. The terms *ethics* and *morals* are often used interchangeably. Indeed, they do share similar attributes, such as value-based judgments about

appropriateness and inappropriateness of human behavior and interactions. Yet, many in the field of counseling and psychology differentiate them as follows: *Ethics* or *ethical codes* are the agreed upon standards of aspirational and mandatory behaviors and practices by the members of professional organizations such as the American Counseling Association (ACA) or the American Psychological Association (APA). These standards guide and inform the professional practice of members and promote the expectation that counselors will protect their clients' welfare and freedoms. *Morals* are defined as behaviors or actions that are based on particular groups' culture and or values. Hence, morals are a more generally defined and culturally influenced system of beliefs. Morals are believed to serve the common good for most members of a society.

## Different Types of Ethics

No discussion of ethics would be complete without acknowledging that counselors face confusing descriptions of various types of ethics. An examination of any textbook on ethics would lead the reader through a general discussion of some combination of philosophical, principle, professional, aspirational, mandatory, and virtue ethics.

*Philosophical ethics* describes the study of ethics through the lens of a theoretical perspective. The theory one chooses to use as a foundation determines how one interprets the rightness or wrongness or worthiness of certain behaviors. Because of its theoretical nature, this type of ethics has limited utility in a counseling practice. In contrast, *principle ethics* are pragmatic in nature. Principle ethics are based on moral principles. They are described as a collection of duties *and* a process that provide counselors an immediate method they can follow in order to remedy an ethical dilemma, and the process establishes a format for ethical practice and decision making in the future. Principle-based decision making centers on one's behavior and choices as they relate to socially acceptable practices.

*Professional ethics* are the agreed upon acceptable practices of a professional organization. These practices are typically codified by the membership and provide a guide for both aspirational and mandatory forms of ethics. *Aspirational ethics* illustrate the highest standard of ethical practice. Counselors whose practice is guided by aspirational ethics understand and act on the letter *and* spirit of the ethical codes. Aspirational ethics

call counselors to evaluate their personal behaviors and motivation as well as the ethical code to ensure their clients receive services that exceed the expected standard of care. Aspirational ethics are often identified in ethical codes as the “best practices.”

*Mandatory ethics* are those minimum standards by which all counselors should practice. Counselors who practice at this level are considering what they “must” and “must not” do; this is practicing the letter, but not the spirit, of the ethical code. Mandatory ethics are often identified in ethical codes as “standards of practice.”

The last type of ethics discussed here is *virtue ethics*. Virtue ethics focus on the character traits of the individual counselor and the aspirational aspects of one’s practice. Virtue ethics are not concerned with solving ethical dilemmas per se. They call upon counselors to examine whether or not they are doing what is best for their clients. Hence counselors focus more on what is desirable for a client rather than on a duty. Meara and colleagues noted that professionals practicing virtuously would aspire to the core virtues of prudence, integrity, respectfulness, and benevolence.

In counseling, practitioners are guided by ethical codes influenced by moral principles and the standards of their profession organization. At a minimum, the codes provide a description of the standards that counselors must meet and those to which they may aspire.

### The Purpose of Ethical Codes

Ethics, or an ethical code, is the set of rules professionals develop to guide the practice of the profession. In counseling, numerous organizations like the ACA and APA have established codes that educate all members of the organization on expected and acceptable ethical practice. Yet, ethical codes have many purposes beyond education.

Researchers in counseling and psychology have noted that ethical codes protect the public by publishing the expected standards of behavior and practice of professionals. Second, ethical codes can protect practitioners when their performance or behavior is called into question. If the behavior in question is in compliance with the ethical code, the counselor behavior is more likely to be viewed as conforming to the standards. The ethical codes are a form of professional self-regulation that, when enforced with fidelity and accountability, deter governmental regulation. Finally, the aspirational components of the ethical codes can serve as a catalyst for improving

practice by encouraging counselors to seek more sophistication and accountability in their practice.

### Foundations of Ethical Decision Making

Ethical decision making is a process fundamental to a professional practice of counseling. Ethical codes of conduct generated by professional organizations rest on the general moral principles that guide counselors’ behavior within professional relationships. Counselors have generally agreed that the moral principles of autonomy, beneficence, nonmaleficence, justice, veracity, and fidelity provide the conceptual underpinnings for ethical decision making. *Autonomy* means that counselors respect and foster their clients’ right to freely choose their actions or behaviors that would be in harmony with their personal desires and wishes. Counselors foster clients’ independence in decision making. *Beneficence* means that as professionals, counselors are called to do good and to promote the general health of their clients. *Nonmaleficence* as a principle means to do no harm. Its origins lie in the Hippocratic Oath that calls upon physicians to avoid any act or practice that may harm a client, even inadvertently. The principle of *justice* calls upon the counselor to be fair, just, and equitable in all practices with all clients. Counselors are committed to treating all clients equitably. *Veracity* means that counselors will be truthful in all interactions with clients, colleagues, and professional peers. The final principle, *fidelity*, calls upon professional counselors to practice in a trustworthy manner by honoring their commitments to clients and other professionals.

These principles are presented to counselors as a unified whole, a set of equally balanced and dynamic concepts that are to be considered in the best interest of the client. Yet, at times, these principles may be in conflict, and hence a potential ethical dilemma emerges. This conflict among the principles is the foundation of the definition of an ethical dilemma. First and foremost, an *ethical dilemma* exists when two or more of the moral principles are in conflict or competition. Consider the counselor whose client clearly threatens to kill his or her intimate partner later that afternoon; the counselor has the legal and ethical duty to warn the identified victim of the potential for harm. By upholding his or her professional and legal obligations, the counselor will breach the client’s confidentiality (limiting fidelity) and possibly limit his or her freedom (autonomy—client may require involuntary hospitalization) in order to

protect the potential victim and client from harm and to do good (reinforcing nonmaleficence and beneficence).

## Ethical Decision-Making Models

Ethical decision-making models provide a systematic framework that counselors can use to examine the origins, nature, impact, and potential consequences of a professional's actions and attitudes. Counselors challenged with an ethical decision may feel perplexed and apprehensive. Ethical decision-making models, if used properly, can guide them along the process of decision making in a logical, consistent, and practical manner.

Ethical decision-making models are based on different conceptual foundations (e.g., theoretical, philosophical, or practice-based) and various schools of thought (e.g., rationalism, moral reasoning, feminism, social constructivism, and social justice). Models derived from these foundations provide an organization scheme and particular perspective that give counselors a method from which to work through and analyze potential ethical dilemmas. According to numerous researchers, there are at least nine documented ethical decision-making models in the professional counseling literature. This entry examines five of them.

Kitchener's 1984 *principle* or *rational* model is one of the more widely used paradigms. This model was drawn from the ethical literature in psychiatry. The premise of the rational model is that relying on personal value judgments, or intuition, was not sufficient, and that clear ethical guidelines were a must for sound decisions. Kitchener, and others, noted that decision makers needed to understand and consider the continuum of thinking, from absolutism (dichotomous, rational, non-contextual) to relativism (multiple influenced, relational, contextual) as they critically considered the facts at hand. Therefore, decisions were derived from a structured process of critical thinking and systematic logic rather than a personal or emotional response.

In 1994, Rest devised the *four-component* model, which was touted as one of the most empirically grounded approaches to analyzing moral and developmental behaviors via the works of Kohlberg and others. According to Rest, because the four-component model was based on a large body of existing research on moral development, it could drive further research and instruction in moral education. The four components include (a) interpret one's actions relative to the potential impact on others; (b) devise a moral course of action that would distinguish the moral ideal;

(c) select the more moral outcome from the choices generated; and (d) act or implement one's choice.

Feminist researchers noted, when they examined models of ethical decision making, that most of them rested on a culturally encapsulated view of the White male's worldview. Much like the criticisms that surrounded Kohlberg's work in the 1970s and 1980s (i.e., that the stage model of moral development and reasoning were based solely on White male experiences), feminist scholars warned that the then current ethical decision-making models suffered from a similar flaw. They stated that these decision-making processes may be too linear, dispassionate, and rational, which would ignore the contextual, personal, and cultural considerations of decision makers and clients. The criticism offered by feminists directly questioned the philosophical underpinnings and universality of the earlier rational and moral development models.

*Social constructivists* have posited that ethical decision making should rely on the interactive and mutually constructed nature of reality rather than the traditional beliefs in an objective reality that exists independent of individual perceptions. Social constructivism asserts that there is no objective reality and that reality is the result of social interactions, system influences, and the resulting perceptions. Therefore, the ethical decision-making process will occur with at least one other person who will engage the other in examining and clarifying the information at hand, so that they can negotiate and mutually determine the best course of action.

*Social justice advocates* and multicultural scholars have also questioned the utility and cultural sensitivity of the traditional models of ethical decision making (e.g., rational and moral development). They recognized that the traditional models excluded or appeared to devalue decision making not grounded in the logical positivist tradition. Herlihy and Watson presented a model of ethical decision making based on a social justice paradigm. Counselors using this model would engage in culturally sensitive and competent interactions that were grounded in collaborative decision making and an awareness of virtue ethics.

## Ethical Decision-Making Skills

Counselors are professionals, and there is an expected set of skills that they should acquire from their training, experience, and education. In order to make sound ethical decisions, counselors must possess and

demonstrate an understanding of the impact, importance, and relevance of their actions.

Cottone identified six decision-making skills or attitudes necessary for counselors. First, counselors must be willing to be decision makers and accept the appropriate responsibility for their clients and practice. Delegating or deferring decisions to others demonstrates a lack of professionalism and personal accountability. The next expected skill is that of an intellectual attitude to deal with the complexities of human interactions in a deliberate and systematic manner. Third, counselors must seek and retain current and accurate professional information in order to be of assistance to clients. The reliance on the professional literature is also a characteristic that distinguishes lay counselors from professional counselors. Fourth, counselors continue their learning beyond their formal education and also engage in continued professional development at conferences and by reading trade journals. Ignorance of changes or improvements in the field is not a valid defense of unethical treatment. Fifth, professionals use a framework for decision making that demonstrates thoughtfulness, sound judgment, competency, and credibility. Systematic decision making demonstrates professionalism and accountability. Finally, counselors must be invested professionally. This means that counselors abide by the ethical code and training practice of their profession and that they maintain their skills over their professional lifetime.

Ethical decision making is critical to the professional execution of a counselor's or a psychologist's duties. The process is meant to be orderly and transparent, so that any reasonable person can understand the rationale for the decisions made. Using a recognized model of decision making demonstrates a counselor's professionalism.

## ETHICAL DILEMMAS

---

Counselors make hundreds of decisions as they work with clients. They use professional skills and knowledge to gather information in order to assess, clarify, categorize, and respond to client concerns. Most often, counselors, after some consideration and reflection, know how, or if, to respond to situations. Yet, on occasion, counselors may find themselves facing uncertainty, confusion, or doubt in relation to their or their clients' concerns, behaviors, or needs. Supervision and peer consultation are two recognized and typically effective methods that counselors use in order to clarify concerns related to clinical or treatment questions. Occasionally, counselors will encounter questions or circumstances that seem to originate from ethical and/or legal concerns. These questions, by their very nature, can create a heightened sense of concern or urgency for counselors.

*Ethics* or *ethical codes* are standards of behaviors and practices agreed upon by the members of professional organizations such as the American Counseling Association (ACA) or the American Psychological Association (APA). Ethical codes include a general rather than a specific description of mandatory and aspirational behaviors and beliefs. Counselors are expected to be familiar with and to adhere to these codes as a privilege of membership in the organization. Compliance with the ethical codes ensures client welfare, standardizes the practices of the professional, and is a means of professional self-regulation. Counselors use these codes to guide their practice and determine the appropriateness and degree of obligations they may have in relation to their clients. Yet, being

familiar with and adhering to ethical codes will not prevent the counselor from encountering circumstances that are confounding and/or confusing. The ethical codes are necessary but not sufficient to prevent counselors from encountering these circumstances or ethical dilemmas.

### Ethical Dilemmas in Context

A dilemma is generally defined as a circumstance or situation that is perplexing because a decision is required between equally unacceptable or unfavorable choices. An *ethical dilemma* incorporates the concepts in the preceding definition *and* is a situation in which there is an apparent conflict of moral standards or imperatives. In essence, to uphold one standard would mean violating another. For example, many of the ethical codes in counseling and psychology are based on what some define as universal moral principles. The most commonly identified moral principles are autonomy, nonmaleficence, beneficence, justice, fidelity, and veracity. Counselors who uphold these principles will support clients' freedom to be self-determining in word and deed (autonomy), will do no harm to clients (nonmaleficence), will do good or promote clients' health and wellness (beneficence), will be fair and equitable in their treatment of all clients (justice), will be trustworthy and uphold their word and promises (fidelity), and will be truthful in their interactions with clients. These moral principles are typically presented to counselors as a holistic set of discrete and equally occurring ideals, yet in reality these principles are in relative contextual tension to each other. Upholding one principle will have some impact, positive or negative, on the others. Counselors may encounter an ethical dilemma when they consider the circumstances of involuntary hospitalization of an imminently suicidal client. The client's freedoms (autonomy) will be restricted or impeded in order to promote good for the client (beneficence) to keep harm (nonmaleficence) from happening to him or her.

### Identifying Ethical Dilemmas

For most counselors, an ethical dilemma is apparent when they encounter a confounding situation in which they feel hindered in their decision making because (a) there appears to be conflict between or inconsistency among the ethical standards, (b) the situation is so complex that the ethical codes offer little guidance,

(c) there appears to be a conflict between ethical and legal standards, and (d) there appears to be a conflict between the moral principles that underlie most ethical codes. Counselors can be involved in ethical dilemmas directly, as in the case of client care or supervisory responsibilities, or they can be involved as a colleague, as in the case of witnessing a peer, supervisor, or supervisee struggle with a predicament. Ethical dilemmas differ from *ethical violations* in that the counselors have not yet engaged in any action that would violate the rights of the client or the ethical or legal standards.

Ethics have their conceptual roots in philosophy and as such are open to interpretation and influence from many sources (e.g., theoretical stance, cultural and personal factors, morals). Because of these influences, ethical dilemmas vary in their degrees of clarity and distinction. Some issues or questions may be readily apparent to some individuals but not to others, and some dilemmas emerge only upon reflection or after consultation or supervision. Identifying, addressing, and resolving ethical dilemmas is a dynamic *process* that requires counseling professionals to do more than simplistically apply the codes with respect for the uniqueness of each situation or circumstance.

Ethics and ethical codes are bounded by the cultural contexts in which they were produced. An act that might appear to be an ethical violation to a White male counselor may not be considered unethical when viewed by first generation Hispanic American female. For example, consider this scenario: Both counselors are providing counseling to male teenagers from Korea. In the course of the counseling sessions, each counselor asks his or her client to have his family attend the next session in order to begin family counseling. At the next week's session, both clients bring their family members to the session. Each family is composed of some combination at least one biological parent, one biological grandparent, a couple of siblings, two cousins, and another person who is generally described as a neighbor or friend. One counselor allows all the family members into the session while the other counselor does not, because the cousins and neighbor or friend are not really family members. Clearly, these two counselors have very different ideas as to what constitutes "family" and who should have access to client information. Both could be practicing ethically according to their interpretation of the ethical codes, and depending on one's point of view, both may be engendering an ethical dilemma as the result of their actions. The questions are these: Which

actions by the counselors promote clients' welfare, and what actions may the counselors need to take to ensure all parties are fully informed of the consequences of their decisions? Dilemmas are difficult and complex events to resolve, because there are no easy, clear, and definitive answers.

### Making Ethical Decisions and Resolving Dilemmas

Being a professional means engaging in behaviors that demonstrate concern for client welfare, accountability, reflective practice, use of best practices, and recognition of ethical practice. Counselors must be familiar with their respective codes of ethics, use a systematic approach to ethical decision making, employ sound judgment and reasoning, and act in a respectful and deliberate manner.

Researchers have identified no fewer than nine ethical decision-making models in the field of counseling and psychology. These models provide practitioners a framework from which they can systematically evaluate a set of circumstances or a situation that may evolve into an ethical dilemma. Although the various schools of thought (e.g., rationalism, moral reasoning, feminism, social constructivism, and social justice) differentiate the models of ethical decision making, they all possess similar steps to use when analyzing a potential dilemma.

Most models comprise at least five steps. Counselors are encouraged to go through these five steps with a peer or supervisor in order to provide an additional perspective. First, counselors are to *identify* the potential problem from as many perspectives as possible. Next, *recognize* all the potential issues or concerns involved for all relevant parties. This is similar to brainstorming, which requires counselors to think and reflect broadly. In the third step, counselors are to review the relevant *ethical and legal codes* and identify points of support, contradiction, or contention. Fourth, counselors are to *generate a list* of probable courses of action related to each concern. From this list counselors will select one upon which to act. If counselors have not utilized a supervisor or a peer, it is at this point in the process that seeking consultation is strongly recommended. The final step of ethical decision making involves *executing* the course of action and evaluating and documenting the results.

By engaging in an ethical decision-making process, counselors should be able to take an action to resolve

the dilemma that is in the best interest of their clients. The counselors' actions may not represent the *ideal* response, as ideal responses to dilemmas are rare. Rather, counselors' responses to ethical dilemmas that are a result of an appropriate use of the ethical decision-making model demonstrate professionalism, deliberation, and sound judgment.

## ETHICS IN COMPUTER-AIDED COUNSELING

---

Technology in counseling began with the advent of the desktop computer over 30 years ago. Success in computer-aided services for career counseling and increased comfort with technology were factors in the computer becoming a mainstay in the therapeutic setting. Research has found that the computer enhances counseling services in the areas of testing and assessment, career decision making, intake interviewing, and

personal counseling, and that it enables maintenance and storage of records in a smaller space and improves cost effectiveness. Although Internet access has provided avenues for filing insurance, advertising services, and providing e-therapy, computer-aided counseling refers to applications that are strictly accessed on a basic computer without Internet access. Expanded uses of computer-aided counseling have challenged mental health professionals to understand and take measures to ensure that all ethical standards are met.

The advantages of computer-aided counseling should not lull therapists into ignoring the ethical challenges and considerations that accompany the use of computer technology. All ethical standards that apply to traditional counseling also translate to computer-aided counseling. Further, as the uses of technology have increased, additional ethical standards have been adopted to address the specific unique challenges.

### Ethical Issues in the Use of Computer-Aided Assessments

One of the fastest growing businesses within the field of psychology is that of computerized administration and interpretation of tests (e.g., the Minnesota Multiphasic Personality Inventory-2 [MMPI-2], the Millon Clinical Multiaxial Inventory [MCMI], the Myers-Briggs Type Indicator [MBTI]) resulting in the adoption of the 1986 *APA Guidelines for Computer-Based Tests and Interpretations*. Currently there are over 500 computerized assessments offering computerized interpretations as well. Benefits of computerized psychological tests (CPT) include that little or no supervision of the test-taker is required, little training is required to administer the test, the computer program may generate the report and interpretation, and overall costs are reduced. Other advantages of computerized tests over traditional versions are that the test-taker makes fewer errors and that fewer errors are made when scoring.

Ethical standards further address implications for the development and sales of CPTs and interpretation services. Manuals with clear statements as to the purpose of the test, instructions for administration, validity and reliability scores, and specific interpretation statements must be provided. Most recently, scoring and test interpretation services are also offered to users through mail service or through computer software packages. These services, while helpful, must be considered in light of their limitations. Interpretations must include specific information that might have influenced scoring, such as ethnicity, education, and

physical disabilities. No test scoring and interpretation service should be used if validity, reliability, and specific interpretation information is lacking. It remains the user's responsibility to use and interpret assessments appropriately, regardless of how the tests are scored and interpreted.

One option sometimes offered by automated scoring services is that of providing a copy of the computerized interpretation. Users of these automated services should first investigate to determine how results may be presented and how the client's confidentiality will be maintained. Some services offer to provide a copy of the interpretation, but such a report should not be provided to the client without an explanation in terms understandable to the client. The explanation should include any implications and potential consequences in the future and how the results will be used.

### Competence

Individuals using any type of assessment must be competent in their use. Before computerized versions of psychological tests were created, individuals without the appropriate education and training were discouraged from using such tests due to the intricacies of scoring and interpretation. The ease of computerized testing and interpretation has opened a door to misuse. The developers of computerized tests assume that the user of the test will be competent through education, training, and experience to administer, score, and interpret the results for each specific test. Ethical standards for the use of an electronic assessment include proper selection, interpretation, scoring, and administration in light of research or evidence supporting the purpose, validity, and reliability of the assessment for use with the individual to be tested. Language and cultural differences, disabilities, and familiarity with computers must be considered prior to selecting a specific electronic assessment. Although many computerized versions of the most popular assessments have been found to be psychometrically equivalent to their paper-and-pencil versions, results of research comparing the validity of traditional tests to that of CPTs have been mixed. Not only must CPT users be knowledgeable about the validity and reliability of the tests, they must also be knowledgeable regarding the computerized interpretation system as well. The computerized versions of psychological tests are to be used as enhancements to clinical interviews and knowledge of diagnostic criteria and not as the sole means of making a diagnosis.

When test administration, scoring, or interpretation is delegated to another, only individuals who are judged to have ability to conduct the tasks competently (based upon education, training, or supervision) should be given that authority. Responsibility for the appropriate use and interpretation of assessments remains with the supervising therapist regardless of how the tests are scored and interpreted.

### ***Informed Consent***

Informed consent for any type of assessment should be obtained from the client or guardian and documented, whether consent is written or oral. A clear explanation of the nature, purpose, procedures, format, and duration of the assessment must be given. The explanation of the assessment must also include fees and potential involvement of others (e.g., law, school). If a client is to provide full informed consent, it is important that he or she understand what the assessment is to evaluate (e.g., competency, disabilities) and for what purpose the results will be used (e.g., treatment planning, custody decisions). If results are to be shared with others, the limits of confidentiality must be made clear before informed consent can be obtained. Particularly when an automated scoring service is to be used, the limits of confidentiality must be detailed.

### ***Test Materials and Test Security***

Although maintaining the security of CPTs may seem easier than maintaining the security of paper forms, manuals are also considered test materials and should be secured when not in use. Many tests are now available through the Internet but come with additional security issues. For counselors who wish to provide testing access via their own Web page to their clients, prior to taking such action, consulting with the test developer for permission is advisable. Legal consultation for the use of copyrighted materials through a Web page is also suggested.

### **Maintenance, Storage, and Disposal of Electronic Confidential Records**

As previously stated, one of the earliest uses of computers in counseling was to maintain client records in computer files. The American Psychological Association (APA) mandates that client files must be maintained and stored under the control of the therapist. It is important in maintaining confidentiality that steps are taken

to protect client identification through methods such as assigning case or code numbers regardless of where records are stored. Just as written files are kept in locked filing cabinets within locked storage rooms, electronic files must have equivalent protection.

### ***Storage of Confidential Electronic Records***

While disks can be stored in the same manner as written files, other procedures are required for maintaining confidentiality of files stored on computers. Basic security measures for individual computers with no Internet access are the use of authenticating measures (user names and passwords). For mental health organizations using a computer network with Internet access, multiple combined security measures have been identified as the most effective. The first layer of protection is using authenticating measures to limit record access to only those working with a specific client. A second layer of protection is the use of an intrusion prevention system that detects suspicious network traffic and protects the network by denying access. Encryption provides a third layer of privacy, particularly when individuals are communicating via e-mail.

### ***Disposal of Electronic Files***

Disposal of electronic files has unique problems. Simply erasing a disk or hard drive is not adequate in destroying files, as computer experts can re-create files with little difficulty. It is recommended that computer disks be physically destroyed, as even overwriting may not totally make the information unreadable. For records deleted from a computer's files, secure file deletion utility programs are available to ensure that files cannot be recovered. When a computer must be replaced, the hard drive may be removed and physically destroyed.

### **Improper Use of Computer Treatment Programs and Unrealistic Expectations**

A variety of computer-based psychotherapy intervention programs are now available (e.g., systematic desensitization). Used appropriately as a part of the counseling process, computer interventions have been touted as being quite effective. Ethical considerations include best practices in counseling, competency in the use of the specific intervention, and too great a reliance on the cognitive to the detriment of an exploration of the affective. Clients may also develop a

belief through the instantaneous computer process that a more rapid behavior change will also occur. Information concerning length of time of therapy, including all computer-aided processes, should be explained as a part of informed consent.

## ETHICS IN RESEARCH

---

Ethical issues in social science research are of crucial importance not only to the individuals involved, but also to society. An understanding of what is and is not permissible arose through decades of debate beginning immediately after World War II, when information regarding how Nazi scientists treated prisoners in their care became general knowledge due to the Nuremberg trials. For instance, prisoners were placed into tubs of ice water to gauge the length of time it took to die from hypothermia; this was done in order to research how to save German pilots shot down over the frigid waters of the North Atlantic. The “high-altitude” experiments, in which prisoners were placed in a decompression chamber so the effects of too-little oxygen could be measured, were especially barbaric. Many subjects had their brains extracted and examined, though they were not dead and had not received any medication—they were, in essence, vivisected. Other experiments included injecting deadly poison into Russian prisoners in order to determine the precise amount of time needed for death and amputating the limbs of prisoners in order to see how quickly they bled to death.

Germany was not the only country to engage in unethical experiments. The Tuskegee syphilis study, which took place in Tuskegee, Alabama from 1932 to 1972, withheld vital information from 300 poor, illiterate Black sharecroppers regarding their potentially fatal illness. The authorities lied about what the farmers had contracted, and the sharecroppers did not receive penicillin—a life-saving medication available at any doctor’s office. Instead, they were told that they possessed “bad” blood. Why would American doctors willingly lie to American citizens, though the lie was potentially life threatening? The government was investigating the effects of untreated syphilis and, by the time the subjects were aware of the nature of their illness, many had already died.

During 1961, Stanley Milgram conducted experiments concerning obedience to authority. Milgram grew fascinated with the subject due to stories told by various Nazis during the Nuremberg trials. Without fail (regardless of the defendant’s rank), each stated the same

thing—they were not guilty; rather, all they did was follow orders. When asked if they found their tasks odious, all said yes, but it made no difference because they had been instructed by a superior. Milgram recruited individuals, ranging in age from 20 to 50, with a variety of educational backgrounds. One individual, the “teacher,” would ask the “learner” questions, and if the reply was incorrect, the teacher administered an electric shock. The shock grew stronger with each successive wrong answer. A wall separated the teacher from the learner, and though they could not see each other, they could hear each other’s voices.

The subjects acting as teachers did not realize it, but the “shocks” being administered were fake. In reality, the “learner” was a confederate of the researcher, and the scream the teacher heard was a tape designed especially for the experiment. The study was conducted to see how far an individual would go if instructed by a superior, even if what he or she did was unethical or dangerous. The results were nothing short of stupefying. Each participant could have stopped the experiment at any time, but no one did. Approximately 65% of the teachers administered a “shock” they assumed to be of 450 volts, strong enough to cause death.

In 1971, Stanford psychologist Phillip Zimbardo conducted his famed “prison” experiment. Zimbardo received a grant from the U.S. Navy in order to determine why it was experiencing problems within its prison system. Zimbardo built a prison facsimile in the Stanford psychology building and hired undergraduates to play both prison guards and prisoners. During the study, both groups of participants started deviating from their assigned parts. The prisoners grew weak and docile, while the guards’ behavior grew increasingly vicious and cruel. Zimbardo had to stop the study when it became clear that the participants were losing control. For instance, the guards became increasingly sadistic by forcing the prisoners to exercise until exhausted, by not allowing the prisoners to use the bathroom (causing them to urinate on themselves), and by preventing “bad” prisoners from sleeping.

## Ethical Decision Making

In the years since the studies listed above were conducted, researchers realized that they needed to reassert an ethical imperative to consider all research as potentially resulting in harm to the participant and

bringing that possibility to bear on the decision to conduct the research or not. In order to achieve this goal, research must be designed to meet certain standards with respect to basic moral, legal, and ethical principles. Individuals taking part in a study must give *voluntary consent*. This can only be given if the individual knows the study’s purpose and is fully aware of the potential costs and benefits of inclusion in it. At no point should someone feel coerced into taking part in a study. The use of force is strictly prohibited, and voluntary consent is designed to prevent just such a scenario from developing.

Each individual involved in the study should give *informed consent*. This can only be given if the subject understands fully any inherent risks (either psychological or physical) that could arise from becoming a participant. In addition, informed consent means that each individual has been told all relevant facts regarding inclusion in the study. If a researcher needs children or adolescents for the study, the parent or legal guardian must give consent. In research using people with illnesses, each participant should be told about other therapies that could possibly be beneficial in treating his or her illness.

Each individual taking part should be told that he or she can expect *confidentiality*. This means that any private or personal information gathered during the course of the study will be seen only by those directly involved in the study. The two primary exceptions to the requirement for confidentiality are (a) the participant is in danger of hurting himself or herself, or (b) the participant is in danger of hurting someone else.

Occasionally, moments will arrive when the desire to conduct first-rate research runs head-on against the rights of likely subjects. No set of ethical rules could ever predict each and every ethical dilemma that might arise when using human participants. In order to make sure the rights and liberties of research subjects are never truncated, *Institutional Review Boards* (IRBs) have been created to assist in reviewing research. The IRB is a group of individuals who review research proposals in order to make sure that researchers do not behave unethically with a study’s participants.

Ethical codes were designed to protect subjects, and the following six principles are considered priority guidelines in research.

1. *Autonomy* refers to allowing subjects or clients to make their own decisions, with the researcher or therapist respecting any choices made.

2. *Nonmaleficence* means doing no harm. The counselor's or researcher's responsibility is to avoid hurting clients, even when the counselor's or researcher's intentions are just.
3. *Beneficence* means doing good for clients or subjects.
4. *Justice* means treating all clients with respect, regardless of their race, color, religion, or creed.
5. *Fidelity* means making honest promises and honoring commitments.
6. *Veracity* refers to truthfulness.

Overall, responsibility for ethical conduct of research rests on the individual researcher, the university IRB, and the researcher's profession.

*Cary Stacy Smith and Li-Ching Hung*

## EUGENICS

---

Eugenics is the attempt to deliberately improve the hereditary, genetic traits of a particular race in order to improve the race as a whole. In particular, eugenics, meaning "good birth," describes the regulation and manipulation of reproduction to reduce the incidence of genetically derived problematic traits while increasing the incidence of ideal genetically derived traits. Supporters of eugenics believe that active human intervention can create a stronger society by gaining a

better understanding of genetic traits and their relationship to societal success. Critics of the eugenics movement believe that such attempts violate individual human rights and may remove desirable traits from a population. Further, the critics believe that eugenicists have oversold the power of genetics and have failed to take into account the environmental influences that affect wealth, morality, and mental health.

### Sir Francis Galton

The origin of eugenics is most frequently traced to Sir Francis Galton, a statistician, biologist, geographer, and sociologist who was the first cousin of Charles Darwin, the founder of modern evolution. Galton made numerous contributions to the field of science, including an understanding that intellectual traits were distributed in a manner similar to that of physical traits and an understanding of the heritability of behavioral and intellectual traits. In addition, he created a single numerical representation to measure the correlation between variables.

Through his work, Galton found that human behavioral traits could be passed down from parents to their offspring. Because of this, he believed that humans had the ability to improve themselves by gaining a more thorough understanding of the laws of heredity. Galton hoped that this understanding would help with the identification of select individuals who exhibited desirable traits such as high intelligence or strong moral character. Those identified as having ideal genes could then be encouraged to marry at a young age and have large families.

Galton was greatly concerned at the rate of reproduction of individuals he believed to be least fit. He believed that individuals identified as having undesirable traits should be discouraged from procreating at all. He recommended public health policies such as segregation, sterilization, and other measures designed to prevent individuals from marrying or having children. Galton wrote that the church was performing a great disservice to its societies by preaching the importance of celibacy amongst parishioners—the very churchgoers who presumably had desirable moral fiber and, thus, desirable genes. Galton further criticized social programs that, by providing aid to the sick and to the weak, enabled undesirable genes to persist in a population.

Hoping that societies would be made up of individuals who were stronger, healthier, and more vigorous than societies of his day, Galton promoted eugenics

practice. He supported teaching laws of heredity and systematically studied factors that encourage large families. To advance his eugenic philosophy, Galton employed his statistical expertise to communicate his findings to those individuals with the traits he deemed desirable such that they might have large families. Galton hoped that societal pressures would influence individuals to conform to eugenic requirements of marrying and child bearing with religious-like zeal.

### Assessing Genetic Abilities

Eugenicists felt that it was important to systematically evaluate the genetic pedigree of an individual. One method to identify genetic desirability was to examine an individual's family tree. Through this process, eugenicists would determine the number of ancestors who had particular traits. Families whose pedigrees included academic or business success, long life, strong moral character, and a healthy constitution would be encouraged to breed prolifically. Those who were identified with an ancestry marred by developmental disabilities, criminal records, or psychiatric disorders would be discouraged from breeding.

Intelligence tests were another important component of recognizing an individual's genetic desirability. Those with mental ages below 8 or 12 could be discouraged from procreating or involuntarily sterilized. Other more direct methods of assessment involved simply looking at an individual's accomplishments. Thus, those who were poor or ill were assumed to have undesirable traits such as a poor work ethic and low intelligence.

### Eugenics in the 20th Century

During the 1930s and 1940s, the Fascists in Nazi Germany most enthusiastically embraced the principles of eugenics. Nazi scientists ordered the involuntary sterilization of mentally ill patients and people with inherited diseases, "euthanized" children termed incurably ill, and encouraged the abortion of fetuses of Jews and other members of what they considered undesirable races. Geijman and Weilbaecher note that in 1933, the Law for the Prevention of Genetically Diseased Offspring was passed, resulting in the involuntary sterilization of 400,000 individuals deemed unfit for procreation.

While extreme forms of eugenics are typically associated with Nazi Germany, many eugenic ideas

and practices were espoused in the United States. The American Eugenics Society was founded in 1923. Those directly and indirectly associated with the American Eugenics Society participated in both positive and negative movements. Some groups pushed for strong and fit communities and exhorted families to strive to be as healthy as possible. Positive eugenics movements were the attempts to ensure that healthy people procreated prolifically.

The negative eugenics concepts drew much more controversy. The assumption behind the negative eugenics movement was that children born to criminals or to the "feeble-minded" placed a great burden on society. The American Eugenics Society placed exhibits at county fairs around the nation to delineate the fiscal impact of each individual born with a mental defect. Some eugenicists recommended euthanasia for children they determined would derive no meaning from life.

While euthanasia continued to be viewed as an extreme position of the eugenics movement, the sterilization of the mentally ill gained broader acceptance among psychiatrists and other mental health professionals during the 20th century. As early as the 1890s, guardians of children and adults in mental asylums devised ways to ensure that their clientele did not procreate. Laws promoting the sterilization of individuals deemed incompetent were passed as early as 1909 in Indiana. By the 1920s, a Virginia law legalizing the involuntary sterilization of men and women with developmental disabilities was argued before the Supreme Court in *Buck v. Bell* and found not to violate the 14th Amendment right of equal protection under the Constitution. The Eugenics Society strongly encouraged the practice of sterilization in the 1930s, during which an estimated 60,000 people with developmental disabilities were surgically sterilized.

In other parts of the country, laws restricting marriage were created to prevent the breeding of individuals deemed eugenically unfit. By annulling and disallowing marriages, states hoped to prevent contamination of the gene pool. The first such law was passed in Connecticut in 1895 and was eventually found unconstitutional by the Supreme Court in 1967.

### Eugenics in the 21st Century

It is commonly thought that the eugenics movement died after World War II. Certainly, government-sponsored attempts to prevent groups of people from marrying or procreating currently garner little support

in the United States. Yet, there continue to be strains of eugenics that permeate the popular culture. The use of genetic education may frequently be used to help individuals understand diseases for which they might be at risk. Today, genetic screening is common in the United States. Parents who learn that their child suffers from a genetic abnormality are faced with the decision to give birth to a child with a genetic disorder such as Down syndrome or to abort the fetus. This practice has recently come under attack in the popular press as being eugenic. Fertility practices have continued to move past genetic screening to genetic planning. The Human Genome Project has created the opportunity to understand the relationship between genetics and the phenotypic traits demonstrated within a particular environment. Procedures such as in vitro fertilization and preimplantation screening give parents some control over a child's genes, allowing for the selection of desirable genetic traits.

For those working in the human services fields, the concept of coerced contraception continues to be debated today. While the discussion of improvement of the society's gene pool is not made explicit, there are still concerns that individuals with certain forms of mental illness need to be prevented from procreation—even if only for a limited period of time. For example, a psychiatric patient finding herself to be pregnant may undergo psychiatric decompensation. The treatment of mental illness may be jeopardized by a possible pregnancy or may be dangerous to a fetus. Other patients may have a severe psychiatric disturbance such that they are believed to be incapable of caring for a fetus. These issues may be particularly pronounced in the care of adolescent females undergoing psychiatric treatment.

## EXERCISE AND SPORT PSYCHOLOGY

---

The impact of exercise and sport on our society is pervasive. They are relevant topics for study both because of their societal importance and because they exert a significant influence on physical and psychosocial development across the life span. This entry provides a brief history of exercise and sport psychology, examines the relationship between counseling and exercise and sport psychology, and discusses changes and challenges for counseling psychologists working in these areas.

### A Brief History

There has been an explosion of interest in exercise and sport psychology over the last two decades even though the first course in sport psychology was taught over 80 years ago, and sport psychology became an organized discipline in North America and Europe in the 1960s. In 1985, the Association for the Advancement for Applied Sport Psychology (AAASP; now known as the Association for Applied Sport Psychology [AASP]) was formed. Membership

in AASP is equally divided between psychologists and exercise scientists. In 1986, the American Psychological Association (APA) created an Exercise and Sport Psychology Division. There are now four journals that serve as publishing outlets for the area: *The Journal of Exercise and Sport Psychology*, *The International Journal of Sport Psychology*, *The Sport Psychologist*, and *The Journal of Applied Sport Psychology*.

### **Counseling and Exercise and Sport Psychology**

Exercise and sport psychology is broadly defined as the scientific study of sport and exercise to enhance competence and promote human development in sport throughout the life span. The two areas share similar historical and philosophical underpinnings. Just as sport and exercise psychologists seek to promote competent performance, counseling psychologists focus on building on one's strengths to enhance psychological functioning. In addition, counseling psychology has enhanced exercise and sport by identifying methods that improve performance, increase adherence to exercise programs, and enhance satisfaction and general well-being in exercise and sport. Conversely, exercise and sport psychology has influenced counseling psychology by demonstrating the positive effects of exercise and sport participation on psychological health.

### **Changes and Challenges**

Three areas of importance related to sport and exercise psychology that have brought recent changes along with challenges for counseling psychologists include a focus on working with athletes, using exercise interventions, and promoting positive youth development.

#### ***Counseling Psychologists Working With Athletes***

The dramatic growth of sport psychology over the last decade has spurred an increase of counseling psychologists interested in working with athletes. Although not typically viewed as a special population with particular needs, many unique and influential factors of athletic systems and subcultures create situations and demands outside of the traditional norms of the manner in which counseling psychologists tend to work. Although the empirical evidence of the

effectiveness of sport psychology interventions is mixed, athletes view the most effective consultants as those who they perceive are interested in sport, establish caring rapport, offer concrete sport-specific advice and feedback, and provide follow-up. Athletes believe that consultants show their interest in sport by attending practices and games, maintaining consistent and sometimes extensive contact, and learning their specific sport.

Although athletes do not always feel it is necessary for consultants to have participated in their sport, they do expect consultants to possess a general understanding of the sport experience and the sport environment in which the athlete is involved. This characteristic often involves working with athletes in different settings and under different circumstances. For example, athletes' needs may differ substantially between try-outs, practice, major competitions, and the off-season. Attending practices and competitions can be time consuming, but these are key opportunities to understand the sport environment, observe the client-athlete in context, gather relevant information, and build the therapeutic relationship. Furthermore, the high visibility of athletes and the public nature of their performances provide the counseling psychologist with frequent evaluations of therapeutic goal attainment. Athletes describe poor consultants as those with bad timing and inappropriate behavior (i.e., crowding them or interrupting precompetition routines).

Athletes are also accustomed to being coached and expect consultants to offer concrete sport-specific interventions and instructional feedback. Counseling psychologists who employ more insight-oriented interventions may find their clients becoming impatient with the pace of the counseling interaction. Athletes appear to respond more positively to specific concrete tasks and expect more active collaboration on the part of the consultant.

The initial contact for consultation services is often made by a coach, a parent, or a sport administrator. By virtue of their initial contact, these individuals become the "client," but rarely do they see themselves as the "patient." This perspective is partly due to lack of experience with sport consultants and psychologists and partly due to an expectation that the consultant or psychologist will turn a team around or "fix" a nonperforming athlete. Thus, it is essential for psychologists to clearly communicate the nature of the consultation relationship with regard to confidentiality, record keeping, program goals, and evaluation

criteria. Considerable effort must be particularly invested to ensure the coach or parent understands the importance of confidentiality and privacy.

### **Exercise Interventions in Counseling**

Counseling psychologists are involved in both the prevention and treatment of mental health difficulties. Presently the most common form of treatment is psychotherapy and, in many cases, medication. Psychotherapy is expensive and can be difficult to access. Recent meta-analyses that have examined the relationship between exercise and the prevention of mental disorders such as depression and anxiety have found a number of positive outcomes for both clinical and nonclinical populations. Research has also shown that engaging in exercise can enhance ability to cope with stress and enhance self-esteem. In addition, research has shown that when exercise is prescribed as a regular component of therapy, therapeutic goals are more frequently met in less time, and continued exercise is related to psychological well-being.

There are a number of benefits of exercise interventions, including affordability, minimal side effects, capacity to reach large numbers of individuals compared to traditional psychotherapy and medication, numerous physical health benefits apart from mental health, and applicability to all ages. However, despite the empirical evidence, many counseling psychologists fail to implement exercise interventions, because they lack experience and knowledge about how to implement and monitor these interventions. Therefore, further research and training, particularly continuing education training, is needed to teach psychologists how exercise interventions should be designed and implemented.

### **Promoting Positive Youth Development**

Promoting positive youth development through sport and exercise psychology is a psychoeducational approach to counseling psychology. Several community oriented approaches to teach life skills through sport have been developed and evaluated and have been shown to be effective. By describing life skills as *skills*, the process of learning these skills parallels the learning of any skill, whether it is throwing a ball, driving a car, or baking a cake. Learning new skills entails explicitly describing, demonstrating, and practicing each component of the skill until it can be used consistently.

Implementation involves knowing both the content of the intervention and *how* to deliver it effectively.

Sport-based life skills programs are designed to help individuals learn both sport and life skills. Therefore, the youth must be able to transfer what is learned in the athletic realm to nonsport settings. The similarity between teaching sport skills and teaching life skills provides an immediate advantage. Both sets of skills must be *taught, not caught*. A Chinese proverb best describes the ideal teaching process: “I listen—and forget, I see—and remember, I do—and understand.”

### **Future Directions**

The future of exercise and sport psychology seems bright, but professional opportunities are limited. Counseling psychologists who wish to work in the area must be more than sport fans or exercisers; they must be prepared to become familiar with a new area with all its inherent challenges, frustrations, and opportunities. Often this means working with young athletes and volunteering. What is so exciting is that pairing counseling psychology with exercise and sport has produced and will continue to produce innovative approaches to improving sport performance, psychological well-being, and physical health. For those counseling psychologists involved in exercise and sport, it also provides an ideal way to meld their avocational interests with their vocation.

## EXTERNALIZING PROBLEMS OF CHILDHOOD

---

Externalizing problems in childhood can be broadly defined as disorders characterized by behaviors directed outward. More specifically, these behaviors typically occur in interaction with another person and are represented by disobedience, aggression, temper tantrums, fidgetiness, and overactivity, and they often result in conflict. Beyond differing in their diagnostic criteria, externalizing problems differ from internalizing problems primarily in their expression. However, there is significant evidence that externalizing problems and internalizing problems occur comorbidly. Broadly speaking, the class of externalizing problems in childhood includes attention deficit disorder, attention deficit/hyperactivity disorder, conduct disorder, and oppositional defiant disorder.

### Externalizing Problems Defined

Though not comprehensive, the next section will provide an overview of some externalizing problems in childhood, guided by the diagnostic criteria of the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)*.

#### **Attention Deficit/Hyperactivity Disorder**

The causes of attention deficit/hyperactivity disorder (AD/HD) are unknown, although it is one of the most commonly diagnosed of the externalizing problems. AD/HD is divided into two distinct categories: the predominately inattentive type and the hyperactive inattentive type. A final category is a combined type. The types are categorized according to the symptoms most predominant in the child.

The most distinguishing characteristic of AD/HD is marked difficulty focusing on a task or activity. Children with AD/HD struggle with successful academic development and often experience challenges with peer relationships. When children struggle primarily with inattention, they have trouble completing tasks and listening to directions and appear to be disinterested even when spoken to directly. When hyperactivity is the predominant symptom set, children demonstrate a high degree of distractive physical and verbal activity, including fidgeting, pacing, and excessive talking. Finally, when the symptom set relates specifically to impulsivity, the children have difficulty waiting for their turn, answer questions before the other person completes the question, and often intrude on others' play and interactions.

#### **Conduct Disorder**

The externalized problem of conduct disorder includes bullying behaviors that include threats to the well-being of people or of animals. Children with conduct-disordered behaviors often get their way through intimidation, including physical fighting. Nonaggressive behaviors may also be exhibited, such as damaging property, stealing, and fire setting. Children diagnosed with conduct disorder have difficulty reading social cues, leading them to interpret the behavior of others as aggressive or threatening. Additionally, these children fail to recognize the impact of their behavior on others and therefore do not empathize with emotional or physical pain or personal loss.

#### **Oppositional Defiant Disorder**

Oppositional Defiant Disorder (ODD) is characterized by the child exhibiting frequent displays of anger, arguing (typically with adults), and refusing to follow instructions. Children diagnosed with ODD often refuse to follow directions, refuse to take responsibility for their mistakes, and appear angry and hostile toward others. Often the child appears to be spiteful or vindictive in even the most mundane situations.

### Diagnosing Externalizing Problems

It is important to note that to be considered significant, all symptoms associated with any of these externalizing problems must be present beyond what is to be expected with normal development and must cause problems with psychosocial and educational

development. Any single symptom cannot lead to a diagnosis of one of the above externalizing disorders, and the behavior must occur in more than one setting, such as in school and at home.

## EYE MOVEMENT DESENSITIZATION AND REPROCESSING

---

Eye movement desensitization and reprocessing (EMDR) is a psychotherapy approach used to process distressing memories that are the basis of a wide range of clinical complaints. Comprehensive treatment includes attention to past, present, and future not only to address overt symptoms but also to increase attributes associated with a positive quality of life.

Eye movement desensitization and reprocessing is an integrative approach originally developed to resolve symptoms resulting from exposure to a traumatic

event. Its clinical applications are directed by a theoretical model that emphasizes the brain's information processing system and that views symptoms as arising when memories are inadequately processed. In addition to the efficacious treatment of posttraumatic stress disorder (PTSD), EMDR is also now used to process all kinds of negative life experiences, such as rejection, failure, loss, stress, and conflict, and to bring these to an adaptive resolution.

EMDR uses an eight-phase approach to directly address the experiences physically stored in the brain's memory networks. Treatment involves processing the past experiences that set the groundwork for the problem, the current situations that trigger the disturbance, and new memory "templates" for adaptive future functioning. During the processing phases of EMDR, the client initially attends to the disturbing memory while simultaneously focusing on an external stimulus (e.g., therapist-directed lateral eye movements, alternate hand tapping, or bilateral auditory tones). Standardized procedures are used that allow the emergence of new insights, memories, and emotions, until the targeted event arrives at an adaptive resolution. The client then recalls the incident with a new perspective, elicitation of insight, resolution of the cognitive distortions, elimination of emotional distress, and relief of related physiological arousal.

### History

EMDR was introduced in 1989 by Francine Shapiro with the publication of a randomized controlled treatment study with traumatized individuals. At that time, the therapy was called eye movement desensitization, or EMD, because it was thought that the eye movements resulted in desensitization of the memory. However, it became apparent to Shapiro that desensitization was only one of the many changes occurring with treatment. In 1991, she changed the name to eye movement desensitization and reprocessing, or EMDR, to emphasize the role of the information processing system in producing the treatment effects.

Because EMDR is an unusual treatment, it originally attracted a number of critics who erroneously argued that its effects were due entirely to a placebo effect. Since then, EMDR has been rigorously researched, and its efficacy in the treatment of PTSD is now recognized. EMDR has been effectively used

in numerous cultures around the world, and more than 100,000 therapists have received EMDR training.

### ***PTSD Research***

Approximately 20 controlled research studies have established EMDR's efficacy in the treatment of PTSD. These studies have compared EMDR to pharmaceuticals and various forms of psychotherapy, with results demonstrating that it is as effective and long lasting as the most researched cognitive-behavioral therapy (CBT) methods. EMDR is recommended as an "A" level treatment for PTSD in numerous international treatment guidelines. The American Psychiatric Association and the U.S. Departments of Defense and Veterans Affairs also rate it in the highest category of effectiveness and research support.

### ***Eye Movements***

As with any form of psychotherapy, the neurobiological underpinnings of EMDR's treatment effects are currently unknown. Several studies have attempted to determine the direct effect of eye movements on EMDR outcome. Unfortunately, most of these studies had methodological flaws, and no definitive conclusion can be made. For example, one study reported a decrease in PTSD diagnosis of 85% for eye movement conditions and 50% for the non-eye movement group, but the results were not significant because of the small sample size. A meta-analysis of these studies reported marginally significant effects for the eye movement condition with clinical populations.

Laboratory research investigating the effects of eye movements on memory has consistently demonstrated strong effects. Numerous studies have shown that eye movements decrease the vividness and emotionality of memory images. Other studies have demonstrated that eye movements produce a relaxation effect, decreasing heart rate and galvanic skin response. Research has also found that eye movements increase cognitive flexibility and access to episodic memories. While it is thought these effects are integral to the EMDR treatment process, the extent to which eye movements contribute to treatment outcome is not currently known. Noted sleep researcher Robert Stickgold has suggested that the eye movements in EMDR may activate many of the same neurochemicals released during rapid eye movement (REM)

sleep, thus facilitating free associations and memory processing.

### **Adaptive Information Processing Model**

Shapiro developed the adaptive information processing (AIP) model to describe EMDR treatment and to predict its effects. This model posits that humans have an inherent physiological processing system geared to process all internal and external experiences and to bring these to an adaptive and healthy resolution. When a current experience is similar to those stored in memory, related networks are activated and relevant information becomes readily accessible. This adaptive system allows us to function smoothly throughout our daily lives as we engage in every type of task, from grocery shopping to work-related projects, from socializing to parenting. New experiences are consolidated in memory when associative links are created between them and other related material, forging connections to numerous other memory networks. Learning takes place, and the individual is able to access the new information as needed.

Although this system typically operates in an adaptive way, Shapiro hypothesized that highly disturbing perceptions may not always be adequately processed. When this occurs, the upsetting experience is not integrated with other memory networks that contain more adaptive information. Instead, the distressing memory is stored in an isolated network, in what Shapiro referred to as an "unprocessed state," with the original sensory components. When this distressing memory is activated, the individual experiences the emotions, sensations, and cognitions endured at the time of the original event. Furthermore, these negative sensations influence the individual's perception of the current event, often resulting in misunderstandings or overreactions. Then a memory of the current event is stored within the dysfunctional memory network, strengthening and reinforcing it. The unprocessed memory network remains isolated and unable to link up with more adaptive and positive information.

Shapiro recognizes that some psychiatric disorders or symptoms are organic in nature and that some functional impairments are caused by a lack of experience or information. However, she maintains that the majority of Axis I and II disorders result from unprocessed earlier life experiences and that this

processing failure results in a pathological pattern of affect, cognitions, behavior, and sense of identity. Furthermore, she argues that most difficulties in coping with current life stressors are a result of unprocessed memories. The presenting cognitive and emotional symptoms are understood to be a manifestation of the earlier memory. Therefore, it is anticipated that the complete processing and resolution of these memories will result in remission of the diagnosis and elimination of the problematic symptoms.

## Treatment

### ***Phase 1—Client History and Treatment Planning***

The first phase of EMDR shares similarities with most psychotherapies, with the identification of the presenting problem, development of a therapeutic alliance, collection of a thorough history, assessment of current function, and determination of treatment goals. In addition to these elements, during the history-taking process, the EMDR clinician seeks to identify the dysfunctional memory networks and related targets for EMDR processing. The therapist inquires about earlier experiences that have laid the groundwork for the presenting symptoms, current situations that are triggering the memory network, and the client's concerns about related future situations.

For example, John sought treatment to help him cope with workplace stress related to a bullying and critical supervisor. John found himself over-reacting with anger and anxiety, his function was impaired, and he was afraid he would lose his job. When the therapist inquired about earlier similar experiences, John explained that as a child he had been the victim of bullying. The therapist and John identified several specific memories of bullying and harassment that still carried an emotional charge for John. They also discussed current triggers for his feelings of shame and incompetence and John's fears related to a future job evaluation.

From an AIP perspective, John's childhood memories were not adequately processed, and were stored in an isolated memory network that contained experiences of humiliation and derogation. This network was not connected to memories of positive experiences such as John's academic accomplishments. Currently, the harsh criticisms of his employer triggered the dysfunctional memory network, and John's reactions were driven by his childhood experiences.

John was unable to shift out of that state or to access material in more positive, and realistic, networks.

### ***Phase 2—Client Preparation***

In the second phase, the clinician ensures that the client has adequate stabilization before proceeding to process the distressing memories, which can be expected to elicit strong negative affect and cognitions. In particular, the therapist evaluates the client's ability to regulate emotion and handle distressing situations. Some affect management techniques may be taught, such as using safe place imagery to shift out of a negative affective state. If the client lacks skills in this area, or if his or her life situation is unstable or chaotic, Phase 2 may extend for a period of time. John's therapist assisted John in developing a list of affect management techniques that he used regularly. These included a range of exercise activities, recreational pastimes, creative projects, social contacts, and meditation. It appeared that John had adequate stabilization and affect management skills.

### ***Phase 3—Assessment of the Target Memory***

The third phase is structured to fully access the memory network by identifying its major sensory, cognitive, affective, and somatic elements. First the client describes the most salient sensory image of the event. Next, the therapist assists the client in articulating a current negative cognition (NC) about him- or herself that is related to the target memory, (e.g., "I'm incompetent"). The NC is formulated in the present tense to activate the information as it is currently stored in the memory network. This also serves to assist the client in recognizing the impact of the past event on his or her current self-image. The client is then asked to specify a preferred positive cognition (PC; e.g., "I'm competent") and to rate how true the statement feels when combined with the image of the event, using the Validity of Cognition (VOC) scale (where 1 = false, and 7 = completely true). This rating provides a baseline by which the client and clinician can assess progress. In addition to offering the client a "light at the end of the tunnel," the PC forges a preliminary associative link between the isolated memory network and the adaptive information that is expressed in the positive cognition.

After this, the client is asked to identify the negative emotions that are elicited by the memory, and to

rate his or her level of distress on the Subjective Unit of Disturbance (SUD) scale (where 0 = neutral, and 10 = worst possible distress). The baseline is used to assess progress. In addition, the specification of the emotions allows both client and therapist to recognize changes in the type of affect experienced during processing. Finally, the client identifies and locates the body sensations that accompany the disturbance.

The first target memory addressed by John was of himself at age 7, surrounded by a circle of children who were calling him names. His NC was “I’m a social outcast”; his PC was “I’m a socially competent adult” with a VOC of 3. His emotions were anger, fear, and shame with a SUD of 9 and a body location in the stomach.

#### **Phase 4—Desensitization**

This phase begins with instructions to the client to focus on the visual image, NC, and body sensations, and then to “let whatever happens, happen.” The client maintains this internal focus while simultaneously moving the eyes from side to side for 15 to 30 seconds, following the therapist’s fingers as they move across the visual field. Other bilateral stimuli (e.g., bilateral hand tapping or auditory stimulation) can be used instead of eye movements. After the set of eye movements, the client is told to “let it go” and is then asked, “What do you get now?” The client reports any changes in the memory or associative material (image, thought, sensation, or emotion). Following standardized procedures, typically the clinician then directs the client’s attention to the new material for the next set of eye movements, or back to the original target. This cycle of alternating focused attention and client feedback is repeated many times, as associations are forged to other memory networks. The client often spontaneously accesses related thoughts, images, emotions, sensations, and memories. As the process continues, he or she usually reports cognitive insights and shifts in affect and physiological states.

For example, during processing, John recalled other incidents of peer bullying and humiliation. His emotional state shifted as different memories surfaced; he experienced a number of insights, including the realization that as an adult he instantly responded with rage whenever he felt criticized. The therapist did not dialogue with John during this process; instead she simply encouraged John to “just notice” as he continued with the sets of eye movements and internal focus. If John’s processing had stalled, the therapist

would have used specialized interventions worded to reactivate processing.

As processing continues, with associations being forged to more adaptive information, there appears to be a shift in how the memory is stored. The client will often report a change in his or her perception of the memory. For example, John realized, “It was only some children who were mean to me; there were others who were actually quite friendly.” He then remembered a number of positive social interactions with his classmates.

#### **Phase 5—Cognitive Installation**

The fifth phase occurs after the targeted issue is resolved and no further distress is reported when the memory is accessed (i.e., the SUD rating is 0). At this point, the client focuses simultaneously on the targeted memory and the PC, while engaging in sets of eye movements. This PC could be the belief developed in Phase 3, or another PC that emerged during Phase 4. The purpose is to incorporate and increase the strength of the PC until strong confidence is apparent (i.e., VOC of 6 or 7). Often processing continues to consolidate the changes in the memory network. For example, as John worked on installing his PC of “I’m a socially competent adult” he stated, “You know, it is the bullies who have no social skills!” He also realized that there were various responses that he could use when he felt criticized. He felt quite energized as information related to his social value and skills was incorporated from other memory networks.

#### **Phase 6—Body Scan**

Phase 6 occurs after the successful completion of Phase 5. The clinician asks the client to focus on the incident and PC and to notice if there is any tension or unusual sensation in the body. Because body sensations can indicate unprocessed aspects of the memory network, an assessment of these sensations is used to detect any residual material. Any identified sensations are targeted with eye movements until the tension is relieved.

#### **Phase 7—Closure**

This phase occurs at session end. The therapist determines whether the memory has been adequately processed and, if it has not, assists clients with the self-calming interventions developed in Phase 2. The client is told that processing may continue after

the session and is asked to maintain a journal to record any new material that arises.

### Phase 8—Reevaluation

Reevaluation takes place at the beginning of every EMDR session following the first. In this phase, the therapist evaluates the memory targeted in the previous session by collecting the SUD rating and assessing the PC. If the work is incomplete, processing of that incident continues. If the work on a specific memory is complete, the therapist will then shift the focus to other related memories. Once these have been processed, current triggers that are activating the memory network and creating distress are targeted. With John, for example, after successful resolution of the *past* childhood experiences of peer bullying, the focus shifted to the *present* conflict with his supervisor. The target was assessed using memories of specific incidents (using Phase 3), and processed (using Phases 4 through 8). Finally a *future* template was developed to assist John in handling future situations in which he might feel criticized or humiliated, and the template was processed according to the protocol. Attending to all past, current, and future aspects ensures that the entire memory network is successfully processed.

As John's childhood memories of peer bullying were resolved, he began to experience himself as a socially competent, vital, and dynamic individual, capable of high functioning in many life domains. The change in the way that the memories were stored in the brain resulted in a profound shift in his self-perception with alterations in cognitive schemas, behavior, and interpersonal interactions. John was now able to choose from various options in responding to his employer's criticisms and was able to resolve those issues in a mature manner.

## FAMILY COUNSELING

---

Family counseling may be beneficial when a family member or several members of the family experience difficulties with communication, balancing home and work, the loss of a family member, trauma, divorce conflicts, issues in blended or remarried families, family violence, substance abuse, or behavioral or school problems in children. Family counselors practice in community mental health agencies, managed care organizations, hospitals, private practice, employee assistance programs, and other settings. They provide individual, couples, and family counseling; prevention programs, including parent education programs; crisis management, and other intervention and educational services. Consumers of family counseling are best served by asking for a referral from someone they trust to find out if the counselor is a good fit for themselves and their family members. It may be necessary to schedule an initial consultation to determine if a particular family will work well with a particular counselor.

### Historical Overview

The field of family counseling evolved as families were changing, in particular after World War II. During that time, the divorce rates increased, and there were more demands on families as a system. In addition, people became more accepting of the idea of seeking help for family concerns. Counselors began to include family members to understand and treat individual psychological problems. During the 1950s,

counselors and therapists sometimes observed that when an individual's problem got better, someone else in the family developed symptoms. A patient's condition might have deteriorated after he or she returned home from a hospital stay. Therefore, therapists started concluding that if individuals were treated in isolation from their families, it might be nonproductive. At that time, there was also research attempting to understand the factors that contributed to schizophrenia.

In the 1940s, general systems theory was developed by the biologist Ludwig von Bertalanffy, who believed that the parts of a system are interrelated and that the whole is greater than the sum of its parts. The implication for family counseling was that one person's behavior is interconnected and interrelated to the behavior of all other family members.

Nathan Ackerman, the "father" of family therapy, was one of the first to work with the whole family. His work was during the late 1930s to early 1940s. In the 1940s, Gregory Bateson and his wife, Margaret Mead, began looking into patterns and organization in communication. Soon after that, Bateson was influenced by cybernetics, the study of how systems are controlled and how information is processed. Jay Haley and John Weakland also conducted research on the dynamics of schizophrenic communication. In 1959 the Mental Research Institute in Palo Alto, California, was founded. Bateson, Weakland, William Fry, Don Jackson, Jay Haley, and Virginia Satir made significant contributions to an understanding of how families and systems work. This is where concepts such as that of *equilibrium*, which is the tendency of families to resist change, and of *repetitive patterns of interaction* were developed. Haley was also influenced by

Milton Erickson, a hypnotist in Phoenix who developed a treatment called Brief Therapy. Erickson believed that people could make rapid and effective changes if they tried something new.

Murray Bowen, the developer of family systems theory, studied families who had a member who was diagnosed as schizophrenic in the 1940s and 1950s. He came to the conclusion that because the family was the unit of disorder, families needed to be treated together. He was interested in how a sense of identity is transferred across generations. He developed the concept of *differentiation of self*, which refers to autonomy relative to one's family as well as having the ability to separate one's thoughts and feelings. Bowen tried to remain neutral and nondirective in therapy, and he is often contrasted with Carl Whitaker, the developer of symbolic experiential family therapy, who was more experiential and provocative.

Salvador Minuchin was a pediatrician who came from Argentina and in the 1960s worked with poor families who faced several problems. Through his work he developed structural family therapy, which emphasized how a family's organization may be helpful or unhelpful. He became a director of the Philadelphia Child Guidance Clinic in 1965 and began an exchange of fruitful ideas with other colleagues. He paid attention to family boundaries and noticed that in families that were chaotic and tightly connected, the parents were too involved with their children. In contrast, some families had parents who were too uninvolved and distant. In 1974 he wrote the book *Families and Family Therapy*, claimed to be the most popular book in family therapy.

During the 1970s and 1980s, family therapy flourished. Several centers for family therapy and training were developed, and already-existing centers became more established and influential. During these two decades, the different models of family counseling and therapy were independent from one another and were led by charismatic pioneers. The therapists were experts who could diagnose and repair a family's dysfunction. In the 1980s, family counseling was impacted by feminism. Women such as Marion Walters, Olga Silverstein, and others advocated for counselors and therapists to be aware of and counteract gender-based power structures.

In the 1980s and 1990s, the field was transformed by postmodernism, which suggested that there are no universal truths, only points of view, and emphasized language and meaning. Since then, counselors have

collaborated and worked as partners with families to create new meaning or useful views through language. Questions are asked in order to learn, reinterpret, and reframe experiences. Social constructionism is the primary postmodern school, and it includes solution-focused, narrative, and collaborative language systems. Solution-focused therapy was developed in Milwaukee by Steve de Shazer and Insoo Kim Berg, who de-emphasized the family's problem or its causes. Michael White and David Eposon developed narrative therapy in Australia and New Zealand and were interested in creating a new narrative with families. The theory of collaborative language systems was developed by Arlene Anderson and Harry Goolishian, who believed that people create meaning through language.

### **Different Approaches of Family Counseling**

Family counselors with an experiential focus have goals for families to develop a sense of togetherness and autonomy, build self-esteem, relieve family pain, and overcome blocks to personal growth. Transgenerational family counselors focus on reducing anxiety, increasing self-differentiation, and rebuilding trust and fairness. Family counselors with an emphasis in structural family theory have a goal of restructuring the family organization, reducing symptoms, and creating flexible boundaries. Behavioral or cognitive counselors and therapists focus on modifying behavioral sequences, eliminating maladaptive behaviors, alleviating presenting symptoms, and restructuring cognitions. Social constructionists emphasize learning, creating new viewpoints, and giving new meanings to problems. Counselors identifying with the narrative approach focus on alternative stories helpful to the family, separating the person from the problem, re-envisioning the family's past and rewriting their future. All approaches have in common building a strong alliance with a family and its members based on trust and respect, assessment and utilization of support systems, and the negotiation of expectations, hopes, and resources to make counseling useful.

### **Family Developmental Life Cycles and Alternative Families**

Family counselors pay attention to the family life cycle because of the different adaptations family members make. When there is a transition from one stage to another, changes and stresses may interfere

with a family's functioning and well-being. For the average American family, life cycles may include leaving home as a single young adult, joining with another person to become a new couple, the family with young children, the family with adolescents, launching children and moving on, and the family in later life. Life cycles and events such as marriage, the birth of a child, retirement, and others may vary according to the family members' cultural or ethnic backgrounds. Other family events such as marital separation, divorce, illness, death, relocation, catastrophic events, loss of employment, and others have a tremendous effect on families and the strategies and the coping mechanisms they develop to overcome such events. Family counselors can be of assistance to families and family members with the stresses of moving from one stage of family life to another or when other disruptions occur in the family life cycle. Cultural diversity, including religion and spiritual background, history of immigration, race, and ethnicity also influence the family life cycle.

### ***Divorced Families***

Family counselors may work with family members when they are in the process of deciding to divorce, during the actual time of a divorce, or after a divorce has taken place. When the decision to divorce takes place, working on problems of custody, visitation, and finances becomes important. Mourning the loss of the intact family and adapting to living apart and not being attached to a spouse are some of the concerns family members can process in counseling. During the divorce process, working on the emotional separation and overcoming hurt, anger, and guilt may become the focus of counseling.

### ***Blended Families***

Family counselors may assist blended families with clarification of the rights and responsibilities of the stepparents, adjustments of children to stepsiblings, cohesion of the newly formed family, and integration of their separate family histories. In addition, family counselors help members deal with unresolved issues of loss and grief. Family counselors may see some members and not the entire family. Family counselors can help the family members gain different perspectives and develop strategies to cope with their new family life.

### ***Single Parent Families***

Single parent families may be the result of choice, but in many cases they are the result of divorce, or the death of a spouse. Family counselors may assist family members with issues of grief and loss and with stresses such as loneliness, financial pressures, sadness, and anger for both parents and children. Family counselors can be useful to families before, during, and after a divorce has occurred. If children are involved, there can be partial or total loss of a parent, and issues of custody become important as part of the counseling process. Mediation may be necessary for the couple to work out areas of agreement, especially when there is a need to coparent. Issues of children and remarriage may arise during the course of counseling.

### ***Gay and Lesbian Families***

In families in which the parents are gay or lesbian, in addition to the above issues, family counselors may help with issues related to living in a homophobic society and to internalized messages that challenge a client's self-validation due to strong cultural and internal nonacceptance and isolation. Issues of coming out of children to their parents or parents to their children are important issues that can be dealt with in counseling.

## **Special Issues in Family Counseling**

### ***Family Violence and Physical and Sexual Abuse***

Family counselors must assess for abuse in the family, noting the extent of danger and the possibility of lethality. Factors included in the assessment are a history of violence in the family of origin, low self-esteem, isolation, economic stress, male dominance, use of weapons, and substance abuse. Couples counseling is contraindicated if counseling is court mandated for treatment of violent behavior either toward a partner or toward children. If the abuse has been revealed in a private session, bringing it into the couples or family work may risk the partner's safety. Unless adequate safety plans have been made, the abuse may not be discussed with the abusing partner.

In regard to child abuse, family counselors are mandated to report incidents of abuse or reasonable suspicion of abuse. When families have been informed that abuse has been reported, they are often shocked, angry, or in denial. The child may change or recant his or her

story of abuse. It is important for the counselor to find ways to prevent further abuse, help family members recuperate from the effects of the abuse, and develop different ways of interacting within the family.

### **Family Counseling and Substance Abuse Problems**

Substance abuse significantly impacts the sense of well-being of the family system. Adults who are addicted to substances affect their own lives and those of their children. The children experience increased risk for depression, behavioral problems, and substance abuse. Child abuse and neglect is often related to drug and alcohol abuse. Other related issues include mental and physical illness, side effects of drugs, family violence, and criminal activity to maintain the addiction. Family counseling can play an important role throughout the treatment process for both the person who is using substances and for family members. Family-based treatments have been found more effective in reducing adolescent drug use and behavioral problems than other treatments. Adolescents tend to stay longer in treatment and benefit more from family-based counseling.

### **Code of Ethics**

The International Association of Marriage and Family Counselors (IAMFC) has developed a code of ethics for family counseling in order to enhance, inform, and improve the professional's abilities to effectively serve clients. The ethical code increases public trust and improves the integrity of the family counseling profession. The most common ethical issues include client welfare, confidentiality, competence, and multicultural issues. The term *privileged communication* refers to therapists' being prevented from testifying in court about their clients without their consent.

### **Licensure and Certification**

The first state to adopt a marriage and family therapy licensure law was California in 1963. As of fall 2006, 46 states as well as the District of Columbia license and certify marriage and family therapists. In general, to be licensed, family counselors must have at least a master's degree and have received supervised experience following graduation.

### **Professional Organizations**

The primary association for family counselors is the IAMFC, and its official journal is *The Family Journal: Counseling and Therapy for Couples and Families*. The purpose of the journal is to advance theory, research, and practice of counseling with couples and families from a family systems perspective. The specialty for family counselors was emphasized in prevention, education, and remediation. The IAMFC was developed in 1992 with Jon Carlson as the founding editor of the journal. The IAMFC sets the practice standards and establishes the professional identity of counselors working with families. The IAMFC is a division of the American Counseling Association. The National Credentialing Academy for Marriage and Family Therapists is an affiliate of IAMFC and is included in several of the state licensure laws in marriage and family therapy. Another professional organization is the American Organization for Marriage and Family Therapy (AAMFT), which publishes *The Journal of Marital and Family Therapy*.

## FEEDBACK IN COUNSELING, IMMEDIATE

---

Counseling is a professional and dynamic relationship that requires clinicians to integrate and demonstrate their intellectual and interpersonal skills. This expectation may well have originated with Sigmund Freud, who required all who studied with him to submit to personal psychoanalysis as part of their academic and clinical training. Today, counselors and psychologists prepare for their professional responsibilities through a series of academic and field-based experiences at the graduate level of study. This preparation focuses on an integration of the intellectual, personal, and interpersonal capabilities of individuals.

Counselors-in-training (CITs) receive instruction in a number of subject areas, including, but not limited to, counseling and personality theories, treatment approaches, human life-span development, cultural competencies, research, appraisal and assessment, clinical issues, and treatment. At different points in their education, CITs will treat clients under the supervision of university faculty or other professionals in order to demonstrate a level of competency in providing clinical treatment.

These hands-on or real-world experiences are identified by many terms: *practica* (plural of *practicum*), *internships*, *clinical rotations*, or *field-based placements*. *Practicum*, the common term used here, describes the initial clinical training CITs experience and may take place in a variety of settings utilizing a variety of training formats. Counselors-in-training may see clients in a university-based clinic or training center. Clients and counselors are viewed either in real time through one-way mirrors by an instructor and the counselor's training group or in the previously described setting but with a videotaped rather than live supervision component. Some CITs will treat clients in a community or school setting where sessions may be audio- or videotaped for feedback at a later time. Although the titles, location, and technologies may differ, the common expectations are that

CITs will provide counseling services to clients; receive feedback, instruction, and supervision on those interactions; and integrate that information into their future treatment of client concerns.

### Feedback, Instruction, and Supervision

The terms *feedback*, *instruction*, and *supervision* seem closely related and yet are distinct and well-defined processes in counselor training. *Feedback* is generally described as a brief process of providing specific and behavioral information to CITs about their interactions with clients. Feedback is both content and process oriented. In a live supervised setting, the CITs' practicum instructor and/or peers give feedback in an oral format immediately after the client session is concluded. Systemic counseling approaches have used reflecting teams, not discussed here, during live observations as a method of delivering immediate feedback to couples and family counselors.

In a field-based or community setting, CITs usually receive immediate feedback only when they engage in cotherapy with a supervisor or other clinician. Many field-based settings are not equipped to have counseling rooms with one-way mirrors and recording technology. Field-based CITs usually video- or audiotape their sessions for delayed feedback, which occurs at the next meeting with the supervisor.

*Instruction* includes the direct teaching of a skill, intervention, or process. Prior to enrolling in a practicum, most CITs have a course on helping skills. Students are taught more observable counseling behaviors through an experiential-didactic program. Regardless of the training model used, CITs receive immediate evaluation on their role-played sessions with peers and are expected to incorporate the feedback in order to improve their skills. Instruction differs from feedback in that skill instruction is task-oriented and assumes the CITs have some skill deficit. The focus of instruction is to increase the CITs' knowledge base in order to improve the application of his or her counseling skills.

Most counselor training programs require that counselors-in-training receive weekly individual supervision of their client sessions. *Supervision* is a training intervention in which CITs meet with their supervisors in order to review and assess the CIT's overall counseling performance. Supervision is an

interpersonally focused interaction, in which the CIT and supervisor discuss the CIT's conceptualization of the client concerns, treatment approaches, and the impact of the client and the training process on the CIT. Supervisors serve in many roles relative to CITs, including, but not limited to, those of teacher, counselor, consultant, and evaluator. Feedback and instruction are elements of supervision.

### Immediate Feedback

There are several models of immediate feedback used in counselor training. Two, live observation and interpersonal process recall (IPR), are examined here. Immediate feedback in counselor training is defined as information and critique provided to CITs by their counseling supervisor or peers immediately following the conclusion of a counseling session. When sessions are video- or audiotaped, feedback is provided as the tape is replayed or immediately following its conclusion.

Immediate feedback models described here differ from directive, in-the-moment interventions that occur while CITs are actively engaged with clients. These supervisory instructional practices such as bug-in-the-ear, an in-session electronic voice transmission to CITs; or bug-in-the-eye, an in-room, computer-assisted feedback to CITs; or supervisory interruptions via the telephone or knocking at the door are meant to instruct and redirect the CIT's process with the client. Immediate feedback models also differ from fishbowl or reflecting team models in that clients are not involved in giving or hearing the feedback.

### Live Observation

In settings where live or real-time observation is conducted, CITs meet with their instructor and or training group immediately after the session for no more than 10 to 15 minutes of feedback. This model is not as widely used as it once was due to the costs of the facilities and faculty time. The model is an outgrowth of the training models of the 1970s and 1980s that were based on humanistic and group process approaches.

Numerous scholars have identified guidelines for giving feedback in this type of setting. They note that the supervisor has much the same responsibilities as a group leader and as such should ensure that the guidelines are followed in order to provide structure and safety to the group members. Live, immediate,

postsession feedback sessions closely parallel the process of group counseling in their development through stages, their intensity, and the initial anxiety of members.

The guidelines highlighted in the counseling literature include the following: First, the CIT should be asked to briefly evaluate his or her performance by indicating his or her strengths and weaknesses. The CIT is asked to speak in behaviorally specific terms about what he or she did or did not do. The focus is kept on the CIT's counseling behaviors, and discussion related to the client or the client's issues is kept to a minimum or referred to supervision.

Second, peer feedback should precede supervisor feedback. Peers are to identify behaviorally specific strengths and weakness in the CIT's performance. Peers are to own the feedback they provide the CIT by directly stating: "I observed . . . , I saw . . . , I witnessed . . ." The supervisor provides his or her feedback last in order to summarize the group's input and address or explore any counseling competencies that are directly related to the CIT's concrete actions.

Third, in the early stages of the training group's development, CITs need to hear a balance of positive and corrective feedback. As the group's cohesion and trust grow, CITs can more readily hear more critical feedback. Fourth, supervisors are encouraged to regulate the flow and quantity of peer feedback. The supervisor should ensure that all peers are heard and that the CIT is not overwhelmed by too much information or processing. Some researchers suggest that the CIT on the "hot seat" be allowed to call a time out or break in the feedback if he or she is feeling overwhelmed.

The strengths of this model include (a) a focus on time sensitive training; (b) CITs are provided opportunities to learn directly and vicariously; (c) CITs exhibit greater skill improvement and increased self-efficacy after observing a peer than after observing an expert; and finally (d) the immediate and intense nature of this process provides students the opportunity to interact at multiple levels of cognitive and emotional functioning. This model of immediate feedback is highly dependent on the quality of the supervisor's leadership skills. Therefore, the weaknesses of this model include (a) a dependence on the supervisor's ability to manage the CIT's normal and expected anxiety, (b) a dependence on the supervisor's ability to focus the feedback process, and (c) the cost of maintaining the faculty and facilities.

### Interpersonal Process Recall

Interpersonal process recall (IPR) is a blend of an instructional method and immediate feedback developed by Norman Kagan in the 1980s. In IPR, CITs are given the opportunity to play videotapes of their counseling sessions in order to examine and bring into awareness feelings and attitudes they may have been experiencing in the session. The supervisor functions as a consultant and inquires as to the CIT's understandings and experiences during the session. The CIT can stop the tape at any time. The supervisor assumes that CITs have knowledge of their own experiences but may or may not have consciously examined them. Because the CIT expresses these thoughts and feelings in the moment, without criticism from the supervisor, the CIT's awareness of factors that influence the therapeutic relationship is enhanced.

The strength of the IPR model is that CITs feel a sense of respect and control in directing the feedback session. The IPR experience also encourages CITs to reflect on their personal processes and experiences in a manner that may help them identify and correct old patterns of ineffective behavior. The IPR process can be time consuming and uncomfortable for CITs who are reluctant to experience the discomfort of self-examination and emotion. Finally, the personal nature of the feedback limits its use, for some, in a group setting.

Immediate feedback and the processing that follows are valuable tools to encourage CITs' growth in the areas of self-assessment, self-awareness, and reflective practice skills. Immediate feedback makes the training process personal and authentic.

## FEMINIST THERAPY

---

Feminist therapy, rather than being a succinct theoretical model, is a philosophy of psychotherapeutic intervention that recognizes the impact of varied social practices on personal well-being. It has its roots in the feminist and equal rights movements of the 1960s, and it embraces the conviction that “the personal is political”—that is, that which affects the person is representative of and ensues from the macrocosm in which she or he lives. Feminist therapists practice from a variety of feminist and psychological theoretical perspectives and represent a diverse group of individuals striving for political and social changes that exemplify justice and equality for all peoples.

The tenets of feminist therapy include, broadly, recognition of diversity in identity and of multiple oppressions, acknowledgment of power differentials inherent in the therapeutic relationship and in society, and responsibility for personal involvement in engendering individual and social changes that equalize power.

### Multiple Diversities and Oppressions

Feminist therapy acknowledges multiple aspects of human diversity that are likely to affect clients' personal well-being, including but not limited to, sex, heritage, race, class, age, physical ability, religion, and sexual orientation. While each of these aspects alone may create personal difficulties for an individual within society, most individuals suffer from multiple oppressions. In large part, providing didactic experiences that illuminate these inequities provides the framework for the therapeutic process. Additionally, feminist therapists remain aware of the complexity of human diversity and of how their own personal attributes and differences from the client may be affecting the process of healing.

## **The Therapeutic Relationship**

Although feminist therapists strive to achieve equality in their therapeutic relationships and to empower their clients, they are continuously aware of the intrinsic power differential, especially early in therapy, that exists in the therapeutic relationship. Throughout the therapeutic process, there is a continuous focus on equalizing the client-therapist relationship and on avoiding taking responsibility for or coercing the client. The intent of this focus is to work collaboratively with clients, who are considered experts relative to their experiences, to achieve goals that are meaningful to them. A strong emphasis is placed on consciousness raising, which assists clients in understanding the context of their psychological distress. Within this relationship, therapists are far more likely to be self-disclosing, especially in relation to their own experiences of oppression and empowerment, than in most formal schools of psychological thought.

## **Social Change**

Practitioners of feminist therapy are active in efforts to bring about change that equalizes social and personal power. Because feminism is multifaceted, the focus of such change efforts may vary greatly; however, personal investment in altering power differentials is considered of primary importance for the therapist and, eventually, for the client. Advocacy requires continuous awareness of both positive outcomes and unanticipated negative consequences of efforts to equalize power and promote justice.

## **Developmental Issues**

While feminist therapy has no formal theory of development, it does view society's construction of what is right and good as having considerable impact on individual identity development. For example, Chowdrow has suggested that girls develop through connection with their primary caregiver, usually a woman, while boys avoid this connection in favor of autonomy. Girls are expected to adhere to common gender role stereotypes, including nurturance (playing with dolls), sensitivity, and cooperativeness. Boys, conversely, are expected to be sturdy, power seeking, and self-determining. Society, in various forms, stresses similar messages in relation to a plethora of other personal attributes.

## **Psychological Suffering**

Feminist theorists' views of psychopathology, or problems in daily living, are, in some ways, dependent on their theoretical stances. However, there is consistent recognition that psychological distress is engendered by environmental conditions, especially those of disproportionate power and limitations of choice. Thus, as Ballou and Brown note, it is difficult to label an individual with a "disorder" and to believe that this "disorder" is located exclusively within the person, while ignoring the context of distress.

Feminist practitioners maintain awareness that the mental health field has its own discourse that may undermine the well-being of individuals who do not meet narrow standards of psychological wellness. The historical underpinnings of psychology are based in a White, male-dominated society that emphasizes independence and competition and values instrumental (formerly known as masculine) characteristics. Thus, the profession often ignores the voices and knowledge of the very individuals that they are attempting to serve. Feminist therapists generally have a much broader view of acceptable emotions, cognitions, and behaviors than those that are deemed appropriate in a society that is replete with injustice.

## **Therapy**

The various theoretical perspectives of feminist therapists provide guidance in resolution of clients' personal challenges; however, there are several techniques and philosophies that link feminist therapeutic practices.

### ***Consciousness Raising***

Feminist therapists utilize consciousness raising to examine the role that social power differentials and bias play in personal distress and relationships. Helping clients appreciate the systematic nature of personal constructions and relationships following from cultural constructions and mandates provides a holistic perspective of mental distress and well-being that diminishes self-blame.

### ***Personal Validation***

In large part, consciousness raising sets the groundwork for supporting clients' worth and engendering

personal empowerment. Feminist therapy is a practice of interdependence and support.

Feminist therapy strives to assist clients in finding their own voices to tell their own stories in ways that are self-validating and self-enhancing. It is a therapy of personal esteem and empowerment.

## FEMINIZATION OF PSYCHOLOGY

---

An increasing number of women are joining the field of psychology. According to the National Science Foundation, the percentage of women receiving psychology doctoral degrees increased from approximately 15% in 1950 to 55% in 1988. In 2002, an American Psychological Association (APA) task force found nearly two thirds of all new recipients of master's degrees and doctorates in clinical or counseling psychology were women. In 1985, 34% of APA membership was female; in 2000 the membership was 49% female, reflecting a 15% increase over 15 years. According to an annual survey conducted by the Council of Counseling Psychology Training Programs (CCPTP), there were on average 29.83 women and 10.75 men enrolled in counseling psychology doctoral programs for the 2004–2005 academic year. The same survey found the ratio of female to male assistant and associate professors in counseling psychology was 53 to 18 and 51 to 27, respectively. For full professors, however, the ratio was 50 females to 58 males. Overall, statistics show that counseling psychology has shifted from a field that was once dominated by males to an academic area consisting mostly of women.

### Understanding the Term *Feminization of Counseling Psychology*

The term, *feminization of psychology*, was coined in order to describe the changing demographics of psychology. Within counseling psychology, however, although reference has been made to its gender constitution, little research has been conducted. In general, confusion has existed regarding how the phrase *feminization* is used. For example, the *feminization of psychology* has often been employed to describe how the sex ratio of women to men is impacting (both positively and negatively) the field of psychology. However, the word *feminization* suggests one is referring to the impact of the female gender on the field of psychology, which shifts the meaning from an essentialist understanding of biological sex to a more constructivist interpretation of the cultural implications of being female. Consequently, it is important to locate the term within the context of sex or gender. Throughout this entry, the term *feminization of psychology* is used to facilitate further understanding of perceived shifts in the field that may result from gender-related change. Finally, the discussion of *feminization of counseling psychology* largely reflects the Western cultural environment within the field, most particularly within the United States.

### Feminization or Gender Prejudice?

How do the perceptions and beliefs of the dominant culture influence the way people conceptualize the increase in the number of women in psychology and, concomitantly, in counseling psychology? It has been demonstrated that, historically, the efforts of women have been less visible than those of men within the field of psychology, despite many contributions of note. It has been evident that women were, for many years, under-represented within psychology across various roles, including those of author, therapist, administrator, and professor. This phenomenon has been attributed to, among other things, a historical cultural White male norm against which gender-related endeavors have been measured and acknowledged. It also likely reflects a societal reality that men often gained access to public roles and professions (including educational opportunities) prior to women. The question of whether a discussion of a masculinization of psychology would have ensued had the male-dominated field persisted has been raised in the

literature. Within this larger context surrounding the changing demographics, a “feminized” perspective might be useful were it to contribute new viewpoints and potentially problematic were it to become yet another norm from which to default. Counseling psychology may differ somewhat from other arenas within psychology, as it is a relatively younger branch of psychology and has not carried as lengthy a history of male predominance. It is also noteworthy that counseling psychology, like other fields, is not a fully evolved entity; consequently, the entrance of women into the profession might be correlated with changes not attributable to its feminization (ethnic, socioeconomic, and other kinds of diversity among psychologists have likely also played a role in broadening the traditional perspectives within counseling psychology).

### **Impact on Status and Prestige**

Historically, fields that consist largely of women (e.g., elementary school teachers, nurses) carry lower social status and prestige than those dominated by men. Some worry that as more women become researchers and practitioners, the field of counseling psychology will lose status. Although this concern has been reflected in general trends in some other professions (e.g., bank telling and book editing), research suggests that the increase in numbers of women in psychology has not *caused* a decrease in prestige. The etiology of this relationship is complicated and likely better accounted for by socialization. Specifically, men have frequently been socialized to pursue prestigious occupations, including those that are more profitable, have better working conditions, and offer greater opportunities for advancement. Women, it has been speculated, often have received the message that they should take up less theoretical space by filling lower status jobs. Finally, the status and prestige of counseling psychology has been impacted by the role of managed care, which limits the type and duration of treatment that practitioners may use.

### **Impact on Research**

Others have linked the increase in numbers of women in the field of counseling psychology to an imbalance in research-practitioner activities. There are more clinical practitioners than there are researchers, and some worry that the scientist-practitioner model (the idea that

research dictates practice and practice dictates research) is waning. Specifically, there has been concern that therapists may rely too heavily on clinical judgment rather than empirically supported treatments. Furthermore, within the research community, some psychologists worry that traditional research methods (empirical techniques) may be replaced by inductive qualitative methods. These fears are also grounded, it should be noted, in the belief that qualitative research is subjective, and therefore less accurate than standard positivist measures. Again, a causal link has been drawn between an increasing number of women psychologists and some aspects of the perceived researcher-practitioner gap. There are inevitably many variables that impact a trend of this nature (e.g., an increase in the number of professional psychology programs that often highlight clinical work instead of research and a decrease in federal funding for community and treatment-outcome mental health research programs).

### **Impact on Psychotherapy**

Special consideration for women and gender has been increasingly represented in the counseling literature and through counseling techniques. In her book, *The Shoulders of Women: The Feminization of Psychotherapy*, Philipson explored how the feminization of psychotherapy affects theory, techniques, and possibly even goals of therapy. If such a phenomenon were to occur, counseling psychology might see a paradigm shift relating to its view of mental health. Thus, the way in which psychotherapy is conducted within counseling psychology might be affected.

With more women entering counseling psychology, there has been a concomitant increase in awareness of gender-related issues. For example, the Division of Counseling Psychology of the APA (Division 17) has a formal group titled Advancement of Women, which is dedicated to “representing the interest of women” in areas ranging from professional support to education and training. With additional research and interest in women and gender, feminist principles seem to have become more prevalent. These principles include contributions that range from an analysis of power and status to a relational view of mental health and therapy to a belief that the personal is political. Feminist tenets have helped to advance both research and practice (e.g., improved egalitarian client-therapist relationships and questioned biased research) by transforming what has been the status quo to a more inclusive

approach. These contributions have generally been associated with the feminization of psychology, but as with concerns outlined previously, they are likely the result of several factors.

With an increase in the number of women in the field of psychology, practitioners and researchers have seemed more willing to question their work structure. Flexible hours, parental leave, and improved reentry policies for employees have been cited as significant shifts in work structure within psychology. With further options for employment arrangements, women and men have had the opportunity to build careers with the ability to create space for additional responsibilities such as family. It is important to note that it is not known whether the feminization of psychology caused a more flexible work structure, only that there is a correlation between improved work conditions and the entrance of additional women into the field. On a final note, the feminization of therapy within counseling psychology may reflect the consequences of a more general reality—that of men departing the caring fields, reinforcing the historical association between helper and caregiver and the female role.

### Future Directions

The notion of the feminization of psychology seemed to elicit a strong reaction from practitioners and researchers in the early 1990s. However, there appears to have been less focus on this topic more recently. Still, some studies have suggested that the increase in numbers of women psychologists is an international trend. Specifically, recent studies by Olos and Hoff and by Boatswain and colleagues found that there were more women than men entering the field of psychology in a majority of European countries as well as in Canada.

Although many psychologists have associated negative concerns with feminization, the increase in numbers of women entering the field has also been related to several positive trends. Again, it is difficult to know whether these factors are related exclusively to changing demographics or if there have been additional circumstances that facilitated these contributions. It has been speculated that due to societal attitudes, although numerical equality or even predominance may exist, this does not guarantee that women will predominately shape the future of the profession. Given the issue's complexity, additional

research is needed to better understand the feminization of psychology and the implications of changing demographics.

## FORENSIC APPLICATIONS

---

Forensic counseling may be defined as the application of counseling values and philosophy to persons involved in the legal process. In order for this to occur, one of four processes must take place. The first is concerned with the counselor's intellectual comprehension of criminal behavior, including sexual crimes, spousal abuse, behavioral problems indicating an antisocial outlook, and continuous criminal offenses. Second, counselors should be aware of deterrence issues and have the ability to diagnose various disorders; moreover, the counselor should be very familiar with the factors that are likely to precipitate illegal behavior. Third, a counselor should be familiar with assessment instruments used in diagnosis and should be able to establish a personalized treatment plan for the offender. Last, the counselor should know how to

initiate a counseling intervention that has a primary goal of eradicating the client's problematic behavior.

### **Custody Evaluations**

Family courts frequently use forensic counselors. For instance, when former spouses contest a judge's ruling regarding custody, an investigation may be ordered to determine the best custodial situation for the child (this is commonly called a custody evaluation). While not obligatory, a custody evaluation is prepared when parents have difficulty reaching an equitable arrangement. A first-class custody evaluation will have the following:

- A bare minimum of one (though it is usually more) separate interview each with the mother and father, with a total of three hours with each
- A minimum of one interview with the child or children with the parents absent
- An interview with the child's preschool, elementary, or high school teachers as well as any other adults that have a connection with the child
- For young children, observation of any contact between the child and the parents
- A criminal background check on each parent

### **Divorce Counseling**

During divorce proceedings, judges often request counseling for couples and their children before agreeing to the attorney's writ of divorcement. Divorce adjustment therapy can aid adults and children during this difficult transition. Children often react to divorce with sadness or resentment or conduct themselves in an inappropriate fashion; consequently, impairment in academic performance occurs. In addition, regression takes place in younger children, and both mother and father report that their child's behavior is what they would expect from a younger child. Any of these symptoms reflects a child experiencing a disturbance, and if the child receives no help, his or her symptoms could grow worse. Mental health counseling aids children and adolescents to come to terms with the changes resulting from the divorce and minimize its influence. An effective counselor assists parents to formulate the best method for managing their children.

Children are not the only individuals needing counseling—their parents need to be taught how to manage themselves throughout the divorce. This is especially true for the individual not seeking the divorce but needing to accept his or her spouse's demand for the

legal termination of their marriage. Common symptoms include depression, anxiety, insomnia, and hypersomnia. The primary goal of therapy in this situation is to help the individual come to terms with the impending demise of his or her marriage.

Many states have the requirement that mediation must be included within the divorce process to ease the disturbed relationship existing between the spouses. Divorce mediation is designed to help the couple find an equitable conciliation regarding both monetary issues and custody for their child or children. After the divorce is finalized, mediation is used to promote cooperation, but the focus is placed on the mother's and father's duties as parents; the specific intent is to capitalize on the child's likelihood for emotional and psychological growth.

### **Anger Management**

Forensic counselors conduct anger management workshops in a variety of settings and are frequent consultants in family and criminal courts. Showing one's anger or losing one's temper is not, in itself, a problem; on the other hand, when an individual acts in an aggressive manner toward someone else, a problem is created. Anger management counseling is common in child maltreatment and family violence cases. If a parent loses his or her control with a son or daughter on a regular basis, the parent may be forced to undergo anger management counseling, or he or she may not be allowed to see the child. After an incident has occurred, the person responsible for the violence will usually enter counseling (the judge requires it) to admit his or her blame regarding any violent acts as well as to learn how to control the anger. Many assaults arise due to a parent's lack of impulse control, and the individual thus charged or found guilty can gain insight and control techniques during psychotherapy. When the counseling is ordered by the judge, the sessions are often overseen by probation officers in order to make sure the perpetrator complies with all rules and regulations.

In anger management training, the counselor attempts to understand what occurs in an individual when that individual loses control due to anger, and the counselor teaches different techniques for the individual to use when angry. These lessons might include, for instance, how to relax by using deep breathing or how to manage anxiety on a daily basis. Techniques of cognitive-behavioral therapy are also used so the client can gain mastery over his or her anger. If needed, the

forensic counselor can send the client to a psychiatrist in order to have medication prescribed.

### **Counseling Victims**

Being the victim of a crime can be a life-threatening event, and many victims find it difficult to come to terms with their injuries. Wounds causing physical disfigurement or those that are physically disabling can cause long-lasting psychic disturbances. In addition, these disturbances can take place even if no substantial injury occurred, for example, when an individual witnesses someone experiencing a criminal assault or an individual barely escapes from being seriously hurt. When an individual experiences such events, he or she may develop posttraumatic stress disorder (PTSD) but could also develop major depression, phobias (specific to an act or situation), the fear of being outside (agoraphobia), generalized anxiety disorder, even a psychotic break with reality.

### **Counseling Adolescents**

When dealing with adolescents, the counselor should remember that illegal actions might be caused by inadequate parenting or from growing up in a highly dysfunctional household. Assessing delinquency is a vital element in the juvenile justice system, because the primary emphasis is on rehabilitation, not punishment. A teen offender might need counseling, educational support, or treatment for an alcohol or drug addiction. If the teen is placed on probation, any therapeutic treatment often decreases the odds of recidivism. This is one reason why adolescents placed on probation must be competently evaluated, and tracking improvement in treatment is essential.

A treatment evaluation procedure contains an appraisal of all indictments as well as a complete examination of any past illegal behavior. For adolescents, the forensic counselor should obtain a copy of academic reports, including records of daily attendance and any data regarding school assessment or classifications. The counselor should see the juvenile in order to evaluate his or her emotional state as well as to identify the presence of any mental problems. If ordered by the judge, the counselor should assess the juvenile's personality using reliable and valid instruments in order to discover any problems, for example, psychopathy, dysthymia, or bipolar disorder. If feasible, it may be that the juvenile's family needs interviewing as well, primarily so the counselor can see family dynamics at work.

A complete psychological assessment will detail, in plain language, the test-taker's results. In addition, the forensic counselor will supply information regarding any logical findings that link the client's known emotional difficulties to his or her criminal behavior. The counselor will give precise detail regarding counseling and will offer prospects concerning whether the individual is likely to recidivate in the future. This is accomplished by showing the client's odds of committing crimes again, whether or not the client has had therapy.

### **Counseling Adults**

Mental health professionals have many opportunities to furnish important data to the courts regarding adult felons. For instance, in cases involving child maltreatment, an assessment of the accused may discover emotional conflicts serving as the foundation for the crime(s), and thus the information gathered can be used to devise a workable treatment plan. If a child is a key witness in a criminal prosecution, counselors may need to testify as to whether the child's testimony is reliable. In cases involving family violence, individuals violating court orders may be assessed to determine their impulsivity as well as any future possibility for criminal behavior.

Many illegal actions are connected to mental and emotional problems that can be successfully treated. In essence, if more criminals received proper therapy, recidivism would likely decline at an enviable rate. However, within many prisons, forensic counseling has been discarded due to increasing costs and the relative incidence of failure. Many courts have stated unequivocally that prisons (both state and federal) and local jails have the ethical responsibility to offer counseling to prisoners, and if the therapy is not provided, the institution could be held liable. Once a prisoner has been released, he or she can be required to receive counseling privately (at community mental health centers with a reduced rate) as a prerequisite for probation or parole, with the cost being borne by the parolee or probationer.

### **Child Maltreatment**

Once an individual has been accused of child maltreatment, he or she will be examined by a host of professionals to gauge whether or not the charge has merit. Counselors are often directed to assess both children and adults to see if a history of ill-treatment exists and to gauge the individual, family, and community factors that might have led to abuse. This

helps to identify a scenario in which abuse might have taken place and to devise therapeutic goals that mitigate the effects of any identified maltreatment. Suggestions might entail the removal of a child from his or her parents' home, the removal of a parent or guardian from the home, restricted visitation rights, abrogation of all visitation, modification or complete alteration of parental custody agreements, psychotherapy for the victim and/or the abuser, and preparation for an eventual family reunion.

When child maltreatment cases are investigated, a forensic counselor is often asked to interview all implicated parties. Various assessment instruments may be used to gauge these individuals' mental ability and to determine whether any disorders or problems are present as well as to establish the existence (or nonexistence) of any potential maltreatment risk factors. All information gleaned throughout this process is provided to the court, with the judge ruling on the admissibility of the counselor's findings.

The majority of child maltreatment cases are tried in family court; however, when the charges are particularly heinous, the case could be moved to criminal court, where the alleged perpetrator will stand trial. Once a case is placed in criminal court, the prosecution must prove beyond a reasonable doubt that the alleged abuser is guilty. Counselors may be called upon to clarify, assess, or analyze data written and compiled by others; to certify that the rules and regulations used by the criminal court were adequate to determine whether the conclusions were reliable and valid; or to explain whether the instruments used for assessment performed as stated by their originators.

## FRETZ, BRUCE (1939– )

Bruce Fretz contributed to the field of counseling psychology in a varied and significant fashion. He left lasting impressions on students within the field, facilitated the development of new faculty, and contributed to the growing profession, all from his position as director of the counseling psychology doctoral program at the University of Maryland. Over 20 years of service that included authoring a quintessential textbook, writing numerous articles, and holding various leadership positions, Fretz epitomized influential leadership in counseling psychology.

### Education and Training

In his early years, Fretz did not plan on nor did he believe in the possibility of attending college. He had planned to drop out of school to work to support his mother and younger siblings, as his father had passed away when Fretz was a young boy. However, after he and other teachers discovered that he had an exceptional talent in mathematics, he was switched to the "college track" in school. This sudden change provided him with a boost of confidence that he could perform academically. From there, he progressed academically in a whimsical fashion, with mentors and teachers handing him opportunities that he accepted, by his own admission, with only a half-understanding of their significance.

Fretz was awarded a full scholarship to Gettysburg College and majored in psychology with the original intent of entering the ministry. As he progressed through his undergraduate schooling, he realized that he enjoyed his psychology courses more than his religion and Greek class work. With mentorship and a recommendation from his advisor, Charles Platt, he applied to and was accepted into a graduate program in counseling psychology at Ohio State University. He obtained his Ph.D. in counseling psychology, and in the year 1965, he and his wife were ready to embark upon a new segment of his life near Washington, D.C.

### Overview of Career

Upon graduating with a doctorate degree, Fretz obtained a faculty position with the University of Maryland's Department of Psychology. After a brief

time at his position, he obtained tenure and an associate professor position, as he was steadily publishing research. Then, just four years after graduating with a Ph.D., he was asked to direct the doctoral program in counseling psychology at the University of Maryland, and he held this position for the next 20 years. His leadership helped build a stable and progressive program from one that had previously struggled with its identity, status, and retention of students. Fretz retired from the University of Maryland in 1995, but he continued to play an active leadership role in various organizations in retirement, including participating in the American Psychological Association Council of Representatives.

Over his years working at the University of Maryland, Fretz was cherished by faculty and students as a competent leader and a warm supportive mentor. Students commented on his passionate orientation toward counseling psychology and his ever-present kindness and support. Colleagues emphasized his ability to work with and achieve collaboration among varying staff personalities. Fretz himself suggested that he owed his teaching success to a specific philosophy he had learned from past teachers and implemented. This philosophy consisted of demonstrating one's enthusiasm in the subject, being student-centered, working hard to make the subject matter interesting, being liked by students, and wanting students and the professor to discover the subject matter together. It seems that his attentiveness to the needs of others allowed him to achieve both popularity and success as a professor and program director.

Fretz was a prolific writer, producing texts and articles that expanded the knowledge of the profession and assisted students in learning. His research was consistently on the cutting edge of counseling psychology research, even from his beginnings as a doctoral student researcher. His dissertation project using factor analysis to examine nonverbal communication in counseling initiated the use of factor analysis for this purpose and also formed the foundation for future study of nonverbal communication's impact on the counseling session. He also was the first to perform a meta-analysis on career counseling research. Other research interests included career counseling, sexual attitudes, preparation for graduate study, and preresirement issues. He also wrote articles to guide students in the field of psychology, which further demonstrated his devotion to preparing and mentoring future counseling psychologists. Through such

articles as *Finding Careers With a Bachelor's Degree in Psychology*, *Preparing for Graduate Study in Psychology*, and *Licensing and Certification of Psychologists and Counselors*, he demonstrated his dedication to the next generation of professionals.

Fretz also cowrote one of the most important and influential textbooks in the field, *Counseling Psychology*, which was written primarily for graduate counseling psychology students. Through this text and his other work, he assisted the field in distinguishing itself through a clear definition and vision. In addition to training students, writing textbooks and articles, leading various organizations, and consulting with other graduate programs, he was also editor of *The Counseling Psychologist*. Clearly, he was working hard to improve the profession, directly and indirectly impacting both students and professionals.

During Fretz's career, he held a variety of leadership positions in the field, culminating with his election as president of the American Psychological Association's Division 17 in 1991. He was the Psi Chi national president between the years 1974 and 1978, and he was elected the board chair of the Council of Counseling Psychology Training Programs in 1978. He assisted in the development of some 30 counseling psychology training programs as a site visitor and consultant over the course of 13 years. Clearly, Fretz epitomized leadership in the field, and he played a critical role in developing counseling psychology programs over the course of his career.

## Legacy

Bruce Fretz's legacy is unmistakable. He was passionate and dedicated to fostering the growth of young psychologists, his own counseling psychology program at the University of Maryland, and the profession of counseling psychology as a whole. He did this via a dedication to passionate teaching, a commitment to leadership in local and national arenas, and a prolific writing career. He was respected by colleagues and students for his leadership style and friendliness, and he will be remembered by all for his commitment and devotion to the field of counseling psychology.

---

## FRIEDLANDER, MYRNA L. (1947– )

---

Myrna (Micki) L. Friedlander is best characterized as a brilliant, warm, and delightful individual whose greatest contributions to the profession have brought family therapy into mainstream counseling psychology. Beginning with the first family therapy articles to ever be published in *Journal of Counseling Psychology* in 1984 and 1985, and culminating in 2006 with her book, *Therapeutic Alliances in Couple and Family Therapy: An Empirically Informed Guide to Practice*, Friedlander has contributed much to our understanding of family communication and change. Throughout her career, she has focused on therapist–client discourse and its implications for effective treatment, particularly in family therapy. Her elegant integration of science and practice throughout her career epitomizes the essence of a true scientist–practitioner.

### Career

Reflecting upon her career, Friedlander characterizes it as more serendipitous than planned. She credits the course her professional life has taken to her interest in language, her relationships with supportive mentors and colleagues, and the impetus of the women’s movement. Her academic career began at Case Western Reserve University in Cleveland, Ohio, where she earned a B.A. in French. She taught French to low-income at-risk children in inner-city Boston, when after 5 years she concluded that she was having a greater impact on her students by talking with them about their problems than by teaching them French.

A chance meeting with a high school friend who was enrolled in a master’s degree program in crisis resource teaching prompted her to consider a graduate degree in a helping profession. Friedlander decided to move to Washington, D.C., where she enrolled in George Washington University (GWU). Once again, a chance meeting, this time with the dean of GWU’s college of education, led her to enroll in a graduate counseling course to try it out. Finding counseling a good match with her interests, she decided to pursue a master’s degree in counseling. It was at GWU that Friedlander met her first mentor, Janet Heddesheimer.

As a new doctoral student at Ohio State University (OSU), Friedlander was assigned Ted Kaul as her advisor. Initially skeptical about the “science” of psychotherapy, Friedlander questioned how one could “study” psychotherapy, an “art” that was traditionally the domain of women (i.e., helping people with emotional problems) until a man (Freud) came along and “legitimized” the therapeutic process by calling it a scientific endeavor. These inquisitive thoughts set the stage for an article she would write in 1992, “Psychotherapeutic Processes: About the Art, About the Science.” Ironically, Friedlander has now been studying the “science” of psychotherapy for over 25 years, trying to show that the “art” can be identified, understood, and taught to students.

In graduate school, Friedlander was initially attracted to Stanley Strong’s concept of psychotherapy as a social system, in which change is brought about by specific processes of interpersonal persuasion. She was particularly influenced by sociolinguistic applications to the study of therapy by Harold Pepinsky, a distinguished faculty member at OSU. When Friedlander began her dissertation in 1979, several OSU faculty (including Lyle Schmidt, Ted Kaul, and Don Dell) had concluded that Strong’s theoretical model needed experimental validation with actual clients in treatment. This conclusion led to her decision to pursue a dissertation using role induction as a persuasive method of enhancing therapeutic effectiveness.

While completing her predoctoral internship at Albany Medical Center in Albany, New York, Friedlander received a call from her advisor, Ted Kaul, alerting her to a job opening at the University at Albany (UAlbany), where there was a doctoral program newly accredited by the APA. Although it was early in her internship year and she really enjoyed clinical work, she decided to apply for the position and try out academia. The decision to accept that position became a

pivotal point in her life; it led to a long, productive career as an academic psychologist at UAlbany. At the invitation of another mentor, Reuben Silver, she also served for 19 years (1984–2003) as adjunct clinical assistant professor at Albany Medical College of Union University in the Department of Psychiatry. Friedlander has also maintained a small private practice since 1983 and meets regularly with a peer supervision group.

In her early years at UAlbany, Friedlander found herself, together with colleague Susan Phillips, to be one of only two female counseling psychology faculty members. While navigating new territory for women in counseling psychology, the two became close friends, colleagues, and coauthors. Friedlander also found mentoring support from two other fellow colleagues, Richard Haase and Monte Bruch.

As a professor in the APA-accredited counseling psychology program at UAlbany, Friedlander has served as director of training for the past 7 years. She finds this role to be one of the most gratifying aspects of her work. She truly enjoys supervising and mentoring students, watching them mature, and seeing them transition through graduate school and into clinical and academic positions. Her warmth and sage advice are widely felt by her former students.

### Collaborations and Publications

A serendipitous meeting at an APA poster session initiated a long-term professional relationship with Laurie Heatherington, who shared many of Friedlander's interests in family and gender issues. Their work together on relational control led them to meet Valentín Escudero, professor of psychology and director of the family therapy intervention master's degree program at the University of La Coruña, Spain. Escudero's subsequent invitation to Friedlander and Heatherington to serve as keynote speakers at a conference in Spain marked the beginning of another significant collegial relationship, including a graduate exchange program between La Coruña and UAlbany. Together, Friedlander, Escudero, and Heatherington authored a book that Friedlander refers to as "the crowning joy of my scholarship," *Therapeutic Alliances in Couple and Family Therapy: An Empirically Informed Guide to Practice*. In this book, Friedlander, Escudero, and Heatherington focus on the interchange between and among family members and the therapist, focusing on the use of language to facilitate the healing of families. The authors use their

conceptual model, System for Observing Family Therapy Alliances (SOFTA), to integrate theory, research, and practice. They use their measuring instruments to demonstrate how positive and negative behaviors on the part of both clients and therapists can either strengthen or weaken the therapeutic alliance.

Friedlander collaborated with two other distinguished researchers, Nick Ladany (a former doctoral student of Friedlander) of Lehigh University and M. Lee Nelson of University of Wisconsin–Madison, to author *Critical Events in Psychotherapy Supervision: An Interpersonal Approach*. Together, they closely analyzed transcripts of dialogues to show how problems in group therapy can be identified, explored, and turned into opportunities for growth. This book offers a practical model of supervision and provides empirically based information within a framework of interpersonal relatedness.

Friedlander adopted a daughter as a "gift" to herself once she earned tenure. Given that her daughter was from Paraguay, Friedlander became attentive to children's ethnic identity development long before this was at the forefront of counseling psychology. As she learned more about the process, she wrote three theoretical articles on ethnic identity and international adoption: "Ethnic Identity Development of Internationally Adopted Children and Adolescents: Implications for Family Therapists," "Adoption: Misunderstood, Mythologized, Maligned," and "Bicultural Identification: Experiences of Internationally Adopted Children and Their Parents."

Friedlander has authored numerous other book chapters, articles, clinical training manuals for family therapy, and measurement instruments, including the *Differentiation of Self Inventory* with former student Elizabeth Skowron. Friedlander also has made numerous noteworthy professional presentations in the United States, Canada, Mexico, and abroad in Spain, Portugal, Italy, and Scotland.

### Awards and Distinctions

Friedlander has earned numerous prestigious awards and distinctions. In addition to being named fellow of two APA divisions, Division 17 (Counseling Psychology) and Division 29 (Psychotherapy), she was awarded the Cambridge (U.K.) Diploma of Achievement in Education in recognition of her distinctive contributions to counseling psychology. She also was awarded the title of Distinguished Psychologist by the Psychological

Association of Northeastern New York (2001) and was a recipient of the University at Albany Award for Excellence in Research (2000). In 1991, Friedlander was named a fellow of the American Psychological Society and of the American Association of Applied and Preventive Psychology.

Friedlander has held many leadership positions in national professional associations. She has been exceptionally active as a member of APA Division 17 (Counseling Psychology), serving as communication specialist, division newsletter editor, vice chair of the Section for the Promotion of Psychotherapy Science, member of the Advisory Council of the Science Vice Presidency, member of a special task force on integrating practice and science, and member of several committees (including the Program Committee, Awards Committee, and Fellowship Committee) and special interest groups (Marital and Family Therapy and Qualitative Research Methods). Friedlander has served on the editorial boards of *Journal of Counseling Psychology*; *The Counseling Psychologist*; *Journal of Marital and Family Therapy*; *Psychotherapy: Theory, Research, Practice, and Training*; and *Psychotherapy Research*.

For Friedlander, teaching, mentoring, supervising students, and making a difference in individuals' and families' lives are the most meaningful and gratifying aspects of her career. Undoubtedly, Micki Friedlander's contributions go well beyond the pages in her books; they touch the lives of so many people.

## FUNCTIONAL BEHAVIORAL ASSESSMENT

---

Functional behavioral assessment (FBA) refers to a range of assessment strategies to identify variables that influence behavior in the natural environment. The purposes of FBA are to (1) define and describe problem behaviors, (2) predict when problem behaviors are likely and unlikely to occur, and (3) identify consequences that maintain the behavior (i.e., the functions of the behavior). Learning theory has provided the foundation for the principles of FBA. A variety of processes are used in conducting an FBA, including direct (e.g., behavioral observations) and indirect methods (e.g., interviews) and functional (or

experimental) analysis. FBA data are used to create individualized behavioral interventions that account for the identified predictive variables and behavioral functions.

## Theoretical Principles

Functional behavioral assessment is rooted in the philosophical perspectives of empiricism, contextualism, and determinism. These positions assume that many problem behaviors are learned, that learning occurs through particular interactions, and that these interactions can be altered to produce desired changes in behavior. Learned behaviors refer to behaviors that occur (or fail to occur) because of how they are responded to by significant others or events in the individual's environment. Principles of operant conditioning contribute heavily to the learning theory principles underlying functional behavioral assessment.

The earliest formulation of operant principles is known as the *law of effect*. This law is based on the observation that voluntary behavior is influenced by its effects, namely, its consequences. According to the early version of the law of effect, behavior that produces satisfying consequences tends to become more frequent over time; behavior that produces discomfort tends to become less frequent. Subsequent revisions of the law of effect recognize the importance of relevant situational cues. That is, a behavior may have positive effects in one situation but negative effects in another situation. As a result, individuals become sensitive to situational cues, especially to antecedent cues that precede their behavior and allow them to determine whether a behavior is likely to produce positive or negative effects. Behavior is influenced not only by the effects that follow it but also by the situational cues that precede it.

During operant conditioning, the consequences of a behavior influence the frequency of the behavior in the future. Any operant behavior can be strengthened or weakened depending on the type of consequences that follow the behavior. Reinforcers are types of consequences that strengthen a behavior. Punishers are types of consequences that cause a behavior to become less frequent. Reinforcers and punishers can be either positive or negative, depending on whether the consequence involves the addition or obtaining of something or the removal or escape of something. Positive reinforcement, then, strengthens behavior through the addition of something desirable (e.g., money, smiles). Negative reinforcement strengthens behavior through the removal

of something undesirable (e.g., chores). Positive punishment weakens behavior through the addition of something undesirable (e.g., social disapproval), and negative punishment weakens behavior through the removal of something desirable (e.g., access to a favorite toy or activity). According to behavioral theory, behavior is not random—those behaviors with strong reinforcement histories continue, and those that have been more strongly punished than reinforced will discontinue.

It should be noted that there are often competing consequences for behaviors. A behavior may be followed by multiple consequences, some of which are reinforcing and some that are punishing. Whether a behavior is strengthened or weakened by those consequences depends on whether the overall pattern of consequences is perceived as more reinforcing or more punishing. For example, adolescents who miss curfew may be reinforced by having increased opportunity to socialize with peers, but they may be punished at home. Some adolescents may perceive the reinforcement to outweigh the punishment and so continue to miss curfew. Others may perceive the punishment as strong enough to deter similar behavior in the future. The strength of the consequence, the delay between the behavior and the consequence, and the frequency of the consequences all play a part in their impact.

There are essentially six functions of behavior. Three of these involve positive reinforcement and three involve negative reinforcement:

1. *Obtain internal stimulation:* A behavior may continue because it provides desirable stimulation to the individual. For example, a child might rock back and forth because it is soothing to do so.
2. *Obtain attention:* A behavior may continue because it draws attention from others (attention that is perceived as reinforcing). For example, a female adolescent might dress provocatively because it results in attention from boys at school.
3. *Obtain activities or objects:* A behavior may continue because it results in activities or the acquisition of objects. For example, stealing is reinforced by the objects acquired.
4. *Escape/avoid internal stimulation:* A behavior might be strengthened because doing the behavior allows the individual to avoid an unpleasant sensation. For example, children with ear infections often pull on their ears because it lessens the pain of the earache.

5. *Escape/avoid tasks or activities:* A behavior might be strengthened because it allows the individual to escape or avoid an unpleasant task or activity. For example, children who play with objects in their desk may be doing so because it keeps them from having to do work they do not like.
6. *Escape/avoid attention:* A behavior might be strengthened by helping an individual avoid unwanted attention. For example, an individual might avoid his or her job because at work, the boss continually degrades and belittles the individual.

Antecedents are also important to consider in an FBA. Antecedents are stimuli that precede behaviors and often provide clues about which behaviors will pay off. They do not, however, cause behavior. For example, a red stoplight sets the stage for the behavior of hitting the brakes, because an individual's learning history suggests that doing so will be reinforced (i.e., it is negatively reinforced by the avoidance of getting a ticket or getting in an accident). Antecedent cues that preceded behaviors that were reinforced in the past tend to set up a pattern for repeating those behaviors when the antecedents appear in the future (so most individuals are likely to brake when they see a red stoplight in the future). Antecedent cues that preceded behaviors that were punished in the past signal an individual not to repeat those behaviors in the future.

Not all antecedents immediately precede behaviors. Some antecedents occur very close to the behavior. For example, a teacher asking students to get out their books serves as an antecedent for a child getting out his or her book. Other antecedents are more temporally distant but still impact behavior. For example, *setting events* refer to conditions that impact the occurrence of the behavior, and they often are more distant. For example, a person might be more likely to do a poor job at work (behavior) if he or she did not get a good night's sleep the night before (setting event). All antecedents need to be considered when doing an FBA.

### Historical Progression

By the late 1960s, the methods used to record behavior in laboratories became known as the *experimental operant paradigm*, whereas the consequences that were programmed and their effects on responding became known as the *principles of operant conditioning*. In the

1970s, researchers began applying the principles of operant conditioning to clinically relevant and socially significant problems. For such applications to occur, methods that had been used to program consequences in the laboratory (e.g., schedules of food reinforcement) needed to be replaced with procedures that could be used in clinical and social settings. Similarly, in the absence of mechanical recording devices, systematic observation became the standard means of reliably detecting changes in an individual's behavior. During the 1970s and early 1980s, the term *behavior modification* was coined. Behavior modification is the systematic and scientific use of behavior principles to improve individuals' thoughts, feelings, and actions. It was during this period that many strategies involved in conducting a functional behavioral assessment were developed.

### Processes and Methods

Behavioral analysts incorporate multiple sources of information when making clinical judgments. Each method employed during the course of a functional assessment involves thoroughly describing the problem behavior(s) and gaining an understanding of the events leading to and following the behavior. The clinician gathers information pertaining to the individual client and the function(s) of his or her behavior primarily through the use of interviews, direct observations, and functional analysis.

#### *Indirect Assessment*

Information gathered via interviews is considered to be the launching pad for each of the other FBA procedures. Naturally, conversing with the client about his or her behaviors is often the first step taken by professionals. Clinicians perform interviews with the client and those individuals interacting with the client on a frequent basis (e.g., family members, teachers) to glean rich information pertaining to the problem behavior. Questions typically are designed to elicit information regarding the events prior to and following the client's behavior as well as details about the behavior itself. The interview format may vary in terms of formality based on the professional's preferences and the needs of the individual client.

The behavioral interviewer attempts to gain specific information in order to develop an individualized treatment plan. During each interview, however, the

clinician is also mindful of building good rapport with the client. It is essential that the questions posed by clinicians comprise an interview schedule that sufficiently elicits specific and accurate information concerning high-risk behaviors, such as violence, suicide, and abuse.

Other indirect FBA methods include rating scales and behavior checklists. These tools are used to identify problem behaviors as well as to ascertain relevant setting events, antecedents, and functions (consequences) for those behaviors. Like interviews, other indirect measures may be completed with the client or relevant individuals in his or her environment.

Subsequent to interviews and other indirect measures, hypotheses are often formulated regarding variables that predict behavior occurrence as well as the consequences maintaining problem behavior. In some circumstances, however, indirect information does not elucidate a clear pattern that can be used to make predictions about behavior. Alternatively, the clinician may want to gather additional information before proceeding with an intervention plan. Behavioral observations can provide additional information with which to form hypotheses or to support or disconfirm those made following interviews. Direct observation is frequently informed by the information gained through indirect methods. For example, a clinician may use the specific definitions of a behavior arrived at through interviews as the basis for observing that behavior in the individual's environment.

### **Behavioral Observation**

Systematic observation procedures are an integral component of this empirical approach to understanding behavior. Indirect assessment relies on the client, or another informant knowledgeable about the behavior in question, to recall and accurately report information. In contrast, direct behavioral observation allows the recorder to witness and immediately record information about the target behavior, antecedents, and consequences. The observer may be the professional conducting the FBA or an individual who works with the client frequently (e.g., group home employee, teacher, parent). Alternatively, the client may perform this form of data collection pertaining to his or her own behavior. For example, the clinician may ask the client to record each time he or she smokes a cigarette. Additionally, the client would record the events occurring before and after the smoking behavior.

The observer should receive training on how to accurately record antecedent-behavior-consequence (ABC) observations.

Clinicians are able to choose from several approaches to observe samples of the client's behavior: event sampling, duration recording, and interval recording. *Event sampling* or *frequency recording* involves counting the number of times that the behavior is seen occurring during a specified time period. *Duration recording* accounts for how long an instance of the behavior lasts. *Interval recording* methods provide an indication of the percentage of prespecified intervals during which the behavior is observed to occur. The observer then extrapolates the sample data to help explain the entire behavior. To help ensure that the observer witnesses the target behavior, it is important to schedule the observation period at times when the behavior is most likely to occur. It is also important that observations are scheduled at times and in places where the behavior is not typically seen. Recording observational data in a variety of settings and times throughout the day will allow the clinician to understand when the behavior does and does not occur and can be useful in developing interventions.

The amount of information gained through behavioral observation techniques is vast and can seem overwhelming during the initial stages of investigation. With time, common themes emerge from clients' data. Ideally, behavioral observation should occur until themes emerge from the data concerning the individual client.

### **Functional Analysis**

Clinicians employ functional analysis procedures to better understand the purpose, or function, of the client's behavior. Although the goals of interviews, behavioral observation, and functional analysis are similar, functional analysis procedures require the clinician to directly manipulate the environment. During interview and behavioral observation sessions, the clinician attempts to understand the client's behavior within the context of his or her everyday life. Interviews and behavioral observation allow the clinician to develop hypotheses about the antecedents and consequences that maintain the client's target behavior. The functional analysis process allows the clinician to test the validity of these hypotheses through experimentation. Identified antecedents and consequences are isolated and altered while the target

behavior is monitored. Often, functional analysis includes four conditions—one in which attention is presented contingent upon the problem behavior being exhibited, one in which escape is allowed contingent upon the behavior, a third in which the client is alone, and a fourth in which no task demands are made and reinforcement is available. The clinician utilizes data kept on the target behavior to determine which environmental modifications have the greatest impact. The results of functional analyses allow clinicians to develop individualized, data-based interventions for clients.

### Developing Interventions Based on a Functional Behavior Assessment

Once relevant antecedents and functions of behavior have been identified, they are used in the development of a plan for remediating the problem behavior. With regard to antecedents, the intervention should decrease or minimize antecedents that lead to the problem behavior as well as increase those that are not shown to lead to the behavior. For example, if it is determined that overeating at dinner is more likely when a person skips breakfast and when he or she is dining alone, the intervention likely would include encouraging the individual to eat breakfast every day and to make plans to dine with others as often as possible. Alternatively, it is important to consider those antecedents that precede appropriate behavior and to increase their frequency. For example, if the individual in the example above tends to eat moderately when seated at the dining room table with the television off, the plan might include encouraging the individual to set up those conditions when eating dinner. Both temporally distant setting events and immediate precursors to the behavior should be considered when addressing antecedents.

Building interventions based on functions is a bit more complicated, because there are several factors to consider. According to behavioral theory, all problem behavior is being reinforced (i.e., only reinforced behaviors continue). One part of the intervention, then, is to find a way to decrease the problem behavior, either by punishing it or by lessening its reinforcement value. However, simply decreasing a problem behavior is unlikely to be effective unless an appropriate alternative behavior is put in its place. If, for example, a child learns that he or she can get access to toys by grabbing them from other children, a plan

might involve making sure that an adult prevents the child from playing with the toy after it is snatched from someone else. The plan might also include punishing the behavior of grabbing toys from others (e.g., by having the child play separately from other children for a brief period). In this case, the plan is to ensure that the behavior of grabbing toys does not lead to the reinforcer of getting to play with toys that have been grabbed. If the behavior of grabbing decreases and there is no behavior to put in its place, it is likely that the behavior may return or another inappropriate behavior (e.g., hitting) might appear. It is important, therefore, to include in interventions a way to promote more appropriate behaviors that might serve the same function as the problem behavior. In the above example, the child might be taught how to appropriately ask for toys he or she wants to play with. The idea is that the child learns to get access to toys (reinforcement) for a more appropriate behavior than grabbing at them.

In considering appropriate behaviors to replace inappropriate ones, it is important to recognize that some individuals will need to be taught those behaviors. In the examples used above, an individual might need to be taught how to eat slowly and mindfully to avoid overeating. Children might need to be taught how to ask others to give them a toy.

Overall, comprehensive interventions based on FBA procedures should include multiple strategies, each of which is individually tailored to the client and based on the specific findings from the FBA. Following the FBA process helps ensure that interventions are based less on the topography (or name) of a problem behavior and more on the circumstances surrounding the behavior for a particular individual. Research has shown that such interventions are more likely to result in reduction of problem behaviors and/or increases in appropriate replacement behaviors.

---

## GAMBLING

---

Gambling has become a major recreational activity in the United States. In the past, legalized gambling was confined to a few states, such as Nevada and New Jersey, but in the past two decades gambling opportunities have expanded. Some form of legalized gambling exists now in all but two states; 37 have lotteries, and 27 have casino gambling. A 1999 survey showed that nearly 90% of the adult population participates in some form of legalized gambling, especially instant lottery games, slot machines, office pools, and card games. In the 23 years from 1974 to 1997, gambling expenditures more than doubled as a percentage of personal income.

While most persons gamble responsibly, between 3.5% and 5% of the general population develops problematic gambling. Pathological gambling (PG), the most severe form of problematic gambling, may affect as much as 1% to 2% of the adult general population, which suggests that more than 2 million Americans suffer from this disorder, with roughly twice that many having gambling related difficulties without meeting the criteria for the disorder as described in *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV)*. PG is characterized by continuous or periodic loss of control over gambling.

Recognized for centuries, criteria for PG were first enumerated in 1980 in *DSM-III*. The criteria are patterned after those used for substance dependencies and emphasize the features of tolerance and withdrawal, both of which have been described in persons with PG and in those with substance dependence.

*The DSM-IV* enumerates 10 specific maladaptive behaviors, and 5 or more are required for the diagnosis.

Research suggests that PG may be even more common among youth. Gambling itself is on the rise; a national survey reported that 82% of respondents had gambled at least once in the past year, with lottery and casino gambling showing the largest rates of increase from earlier surveys. The psychosocial costs of PG include financial, legal, employment, and relationship difficulties as well as psychiatric complications such as depression, substance misuse, and suicide.

Although PG is widely conceptualized as an addiction, its classification remains controversial. Some experts have included PG as part of an "obsessive-compulsive spectrum" of disorders, while others have linked it with impulse control disorders, such as compulsive buying and kleptomania, or even to the mood disorders.

One quarter to one third of all pathological gamblers are women. Women tend to begin gambling later in life, often in their early 30s, while men start in their late teens or early 20s. Women tend to have a more rapid progression to pathological gambling, a phenomenon known as *telescoping*. Special populations at risk for developing PG include adults with mental health or substance use disorders, persons who have been incarcerated, African Americans, and persons of lower socioeconomic status.

Persons with PG are highly likely to have comorbid mood and anxiety disorders and to misuse substances. Other impulse control disorders (e.g., compulsive buying, kleptomania), and attention deficit hyperactivity disorder are also frequently comorbid with PG. Lifetime drug or alcohol dependence has been consistently reported in persons with

PG, and one survey showed that the rate of alcohol or other drug abuse was nearly 7 times higher among persons with PG than among nongamblers or recreational gamblers. From 30% to 50% of treatment-seeking pathological gamblers have histories of substance misuse.

Personality disorders are also relatively common in persons with PG, although there is no specific “gambling personality.” A small but significant subset of persons with PG has antisocial personality disorder, which appears to run in families.

Researchers have attempted to identify subtypes, but this work has not been empirically validated or led to clinically meaningful distinctions among persons with PG. Perhaps the most widely discussed scheme is the distinction among the “escape-seekers” and “sensation-seekers.” Escape-seekers are often older individuals who may gamble out of boredom or to fill time, and they may choose passive forms of gambling, such as slot machines. Sensation-seekers tend to be younger and prefer card games or table games, which involve active input on the part of the gambler.

An association between crime and PG is well established. The prevalence of criminal activity among pathological gamblers has been estimated to range from 20% to 80%. Illegal behaviors reported by persons with PG include writing bad checks and engaging in embezzlement, larceny, tax fraud, and prostitution (among women). The addictive nature of PG is thought to represent an important criminogenic factor.

There have been no careful longitudinal studies to determine its natural history, but PG is widely assumed to be chronic with a continuous, unremitting, or episodic course. Several phases have been described in the progression of PG. During the “winning” phase, increased accessibility of and exposure to gambling-related activities are listed as causes of the gradual progression from social gambling to PG. Many pathological gamblers are thought to derive a substantial proportion of self-esteem from gambling and rely on gambling to manage their disappointments and negative mood states. A string of bad luck or unexpected losses leads to the “losing” phase, a phase that centers on the behavior known as *chasing*. With *chasing*, the gambler desperately attempts to recover the lost money. Wagering is more frequent and often in larger amounts. The gambler may lie to important persons in his or her life, including spouse, parents, and children in order to hide losses. The uncontrollable spiral of losing and chasing losses leads the gambler to the

“desperation” phase, in which the gambler may begin to engage in illegal activities to support the gambling problem. Fantasies of escape and thoughts of suicide are reportedly common during this phase. Some gamblers may experience a fourth phase of “giving up” or hopelessness and may seek treatment, often at the insistence of others. Depression, thoughts of suicide, and stress-related symptoms, including hypertension, heart palpitations, sleep disorders, or gastrointestinal distress may occur.

PG can wreak havoc in nearly all domains of the pathological gambler’s life, including the social, financial, professional, and personal spheres. Persons may begin gambling as a hobby or way to socialize. As gambling interest progresses, the gambler may begin to isolate himself or herself from family or friends; many will develop feelings of loss of control, guilt, or shame in relation to their gambling. One of the first casualties of PG is the loss of support and trust of family members, including the spouse. Work-related problems develop, as urges and thoughts of gambling are difficult to control, resulting in absenteeism or poor work performance; job loss is not infrequent. Bankruptcy filings are relatively common among persons with PG, and in one study nearly 44% of persons with PG reported having no savings or retirement funds; 22% had lost their home or automobile or had pawned valuables to pay off the gambling losses. In some cases, the consequences of PG can lead the individual to attempt or complete suicide. Attempted suicide has been reported in from 17% to 24% of Gamblers Anonymous members in treatment for PG.

Family history data suggest that PG, mood disorders, and substance misuse are more prevalent among the relatives of persons with PG than in the general population. Twin studies also suggest that gambling has a heritable component. Functional neuroimaging studies suggest that among persons with PG, gambling cues elicit gambling urges and a temporally dynamic pattern of brain activity changes in frontal, paralimbic, and limbic brain structures, suggesting to some extent that gambling may represent dysfunctional frontolimbic activity.

There is no standard treatment for PG, but therapeutic approaches have emphasized individual and group psychotherapy, 12-step programs, and inpatient programs. Research suggests that cognitive-behavioral therapy can be effective, particularly when combined with motivational interviewing. Gamblers Anonymous, a 12-step program founded in 1957, may

be helpful. Unfortunately, attendees often drop out in the first year, reducing its potential effectiveness. Inpatient treatment and rehabilitation programs similar to those for substance use disorders may be helpful for selected patients. The use of medications to treat PG is being actively researched but is complicated by a high frequency of placebo response and high dropout rates. The opioid antagonist naltrexone has been shown to be more effective than placebo, as has the opioid antagonist nalmefene, which is not available in the US.

## GENETIC COUNSELING

---

The profession of genetic counseling, a relative newcomer to the field of counseling, has been on the leading edge of innovation since its inception in the 1970s. Significant advances in medical technology over the past 40 years have led to breakthroughs in genetic testing along with subsequent improvements in the prevention, analysis, and treatment of genetic disorders. Due to these remarkable developments, the profession of genetic counseling has come to the forefront to meet the challenges of the 21st century and beyond.

Genetic counseling is most commonly defined in the literature as the evaluation of a couple's medical and family history in order to determine the health hazards to a fetus due to a variety of causes. These include exposure to teratogens in the womb (environmental risk factors that adversely affect the fetus), chromosomal damage, and genetic birth defects. According to the Centers for Disease Control and Prevention, approximately 3% of babies are born with birth defects each year.

Some of the most commonly known genetic disorders, such as Down syndrome, congenital heart defects, cystic fibrosis, muscular dystrophy, and spina bifida, are the result of an inherited condition or a genetic mutation at conception or in vitro. Disorders such as Huntington disease and Marfan syndrome can be inherited from just one parent. Other diseases such as Tay-Sachs and sickle cell anemia are found in certain ethnic racial groups and are inherited when both parents carry the gene for the disorder.

Not every expectant parent is a candidate for genetic counseling or testing. Couples are encouraged to seek out this option when the following risk factors are present:

- Prenatal screening tests show abnormalities.
- An amniocentesis procedure uncovers chromosomal abnormalities.
- There is a family history of birth defects or an inherited disease.
- Previous children born to the couple have genetic disorders or existing birth defects.

- The expectant parent is over the age of 35.
- The expectant parent has had two or more miscarriages, a stillbirth, or a child who died early in infancy.
- Either parent is a member of a particular ethnic or racial group that has a high incidence of genetic predisposition to a disease or disorder.
- There is a history of drug and alcohol abuse in either parent.

When expectant parents decide to pursue the option of genetic testing, sophisticated tests are performed to identify the possibilities of passing on inherited disorders. The test results are then analyzed and interpreted by genetic counselors who work in conjunction with the couple's doctor to help parents assess their options and make decisions about how to proceed with the pregnancy as well as the subsequent birth of the child. Genetic counselors function as part of a healthcare team and act as advocates and referral sources to the families they serve. Supportive counseling is also provided to couples who are dealing with emotional issues that arise as a result of learning that their child has a serious genetic condition.

### **Preparing for a Career in Genetic Counseling**

People enter the field of genetic counseling from a variety of specialties, including nursing, social work, genetics, biology, psychology, public health, and counseling. Genetic counselors are highly trained health professionals with specialized education, usually at the master's degree level. Training includes courses in medical genetics, communication, critical thinking and counseling skills, psychosocial assessment, case management, and the legal and ethical considerations inherent to the profession.

In order to be certified as a genetic counselor by the American Board of Genetic Counseling (ABGC), an individual needs to complete academic and supervised clinical training at an accredited graduate program. To date, there are 22 fully accredited genetic counseling programs in the United States, 7 with "provisional accreditation" or classified as "recognized new programs" by ABGC and 1 with "probationary accreditation." Training programs go through a rigorous evaluation process in order to receive accreditation by ABGC. There are also numerous international programs located in Australia, Canada, China, Cuba, France, Israel, Japan, the Netherlands, Norway, Saudi

Arabia, South Africa, Spain, Sweden, Taiwan, and the United Kingdom.

Candidates for certification in the United States must also pass two exams: a general one assessing human genetics knowledge and a specialized genetic counseling exam. These exams are offered in 2-year cycles, and an individual needs to pass both exams in two consecutive exam cycles in order to become an ABGC Diplomate and Certified Genetic Counselor. Professional certification is voluntary, and an individual needs to be recertified every 10 years in order to retain the right to use the registered title of Certified Genetic Counselor. Doctors and nurses specially trained in the field of human genetics also provide genetic counseling.

Demographic information on genetic counselors is collected every 2 years through a detailed professional status survey. The number of certified genetic counselors has increased from 673 in 1993 to a total of 2,035 in 2005. The field continues to grow as new areas for professional development are created. The 2004 survey indicated high job satisfaction in most areas, with the exception of the possibilities for advancement in the field. A portion of the respondents reported that they were considering leaving the field due to job burnout, changing professional interests, and limited opportunities for advancement.

Traditional genetic counselors that specialize in prenatal counseling work in a variety of settings, including medical centers, hospitals, and private practice. A number of genetic counselors work in administrative and research capacities. Today, however, increased opportunities in the field have opened up new career avenues, including those in business, education, and public policy. In 2002, the median income for genetic counselors with master's degrees and up to 5 years of clinical experience ranged from \$47,000 to \$56,000 per annum.

### **A Historical Perspective**

The first class of master's degree level genetic counselors graduated from Sarah Lawrence College, in Bronxville, New York, in 1971. The National Society of Genetic Counselors was incorporated in 1979. Its vision was to become the voice, professional authority, and advocate of the genetic counseling field, and its stated mission was to uphold the burgeoning profession as a distinguished and legitimate part of the healthcare delivery system in this country.

As early as 1973, genetic counseling professionals began to reflect on the feasibility of starting a

professional society at the International Genetics Meeting in Paris. In 1977, the idea took hold with a group of graduates and students from the Sarah Lawrence College training program. By April 1978, a committee to form the society was established and bylaws were considered. However, the society did not have a smooth beginning. At a meeting in Williamsburg, Virginia, to discuss the training role and function of genetic associates, a highly vocal group of physicians protested the use of the term *genetic counselors* to define master's level professionals in the field. They also protested the plan to exclude medical geneticists (physicians with training and fellowships in medical genetics) from full membership in the new society.

By June 1979, after consulting with legal counsel, the title of "genetic counselor" was adopted by the bylaws committee in spite of the continued protests by some in the medical profession. The society took on the name of the National Society of Genetic Counselors (NSCG), and the first two issues of the society's newsletter had been published. Additionally, regional districts had been established, the bylaws had been filed, and the society had been incorporated in New York State by October 1979. Two of the officers in the fledgling society were appointed to the American Board of Medical Genetics as of 1980, further legitimizing the profession. The organization continued to grow and expand throughout the 1980s, and in 1992 the American Board of Genetic Counselors became a separate entity from the American Board of Medical Genetics. Henceforth, the ABGC became responsible for the accreditation of training programs and the certification of genetic counselors, while the NSGC continued as the advocacy and education arm of the profession.

### Recent Innovations

The field of genetic counseling continues to diversify and grow. Genetic counselors come from a variety of backgrounds, such as teaching, graphic design, molecular biology, nursing, fundraising, and the public health arena, and a number of them have multiple degrees. Their former training and multiple degrees make these individuals' skills increasingly marketable in a changing field.

Genetic counselors can be found working in a number of nontraditional settings. These nontraditional roles include conducting research in biogenetic businesses and universities, teaching genetic counseling training programs, and working in diagnostic

laboratories, Internet companies, the pharmaceutical industry, administration, and public health. According to the most recent professional status survey, an increasing number of genetic counselors are becoming health consultants and going into private practice.

## GERONTOLOGY

---

Gerontology is defined as the study of aging, focusing on the physical, social, and psychological aspects of older adulthood. In the most general sense, gerontology draws from diverse disciplines covering all aspects of the aging process in people and animals.

Gerontology is made up of professionals from areas such as nursing, nutrition, psychology, medicine, pharmacology, sociology, and other social-service related fields focusing on the aging experience. Whether they are focused on research or applied science, gerontologists have a mutual interest in the increased understanding of aging and aging mechanisms and an overarching goal of the promotion of successful aging.

In a youth oriented society, aging may carry a negative connotation. Ageism, prejudice or discrimination based on an individual's age, is manifested in negative views of aging held by the general public. One such stereotype is that all older adults are the same, with increasing homogeneity occurring simultaneously with aging. Myths of the aging experience include erroneous beliefs that older adults are rigid, sickly and frail, cognitively impaired, and dependent on others. However, existing literature clearly refutes these stereotypes of an aging population, and the field of gerontology continues to combat ageist misperceptions.

### Physical Aspects of Aging

Much attention has been given to the specific biological processes that occur during aging. Although to date there is not consensus in regard to the causes of aging, there is general agreement that the physical signs of aging result from the body's natural changes in tissues. In older adults, *stroma* (connective tissue) increases, while *parenchyma* (functional tissue) decreases. This process occurs throughout all organs of the body and likely works in conjunction with hormonal changes, resulting in a general aging pattern experienced by most healthy older adults. Physical changes are a normal product of aging and generally occur in the skin, hair, body build, mobility, cardiovascular, respiratory, excretory, digestive, reproduction, nervous, and immune systems. Sensory organs are affected as well, leading to changes in vision, hearing, balance, taste, and smell.

Although the disease process is not automatically indicated with aging, chronic degenerative diseases may assert themselves in older individuals, including diabetes, arthritis, arteriosclerosis, osteoporosis, gout, and anemia. Symptoms such as inflammation, pain, cough, and rigidity may result from injuries incurred over a life span.

Although physical changes occur in the sexual response cycle, sexuality remains an important part of life for older adults, and sexual intercourse can be a

satisfying experience. Research gives no indication of increased health risks involved with having sex as an older adult. In fact, one study showed that those who continued to have sex frequently after the age of 60 had a more active sexual response cycle, had increased hormone flow, reported higher levels of happiness, and indicated living exciting lives.

## Social Aspects of Aging

### *Retirement*<sup>†</sup>

Retirement is the decision-making process and behavioral transition spanning work and leisure activities that many encounter later in life. Planned retirement is a relatively new phenomenon, as prior to the early 1960s, retirement was often a consequence of falling ill or being laid off from a job. As Social Security benefits and earnings increased, retirement became increasingly viewed as favorable and a right earned for a lifetime of hard work.

Transition into retirement is less clear-cut than it once was, when it was a complete withdrawal from the workforce and from work-related activities. With the current economy, some older adults find that they do not have the option to retire, but instead must continue working in order to survive financially. In contrast, those with a higher socioeconomic status may strategize to create a unique transition into retirement. Rather than completely withdrawing from the workforce, these older adults re-enter the work force for social or cognitive benefits, utilizing this period of their life as a time to pursue goals or interests other than their original employment.

### *Social Security*

Social Security, or benefits provided to elderly persons through social programs, was first established in 1935 by the New Deal's Social Security Act. Although the development of social security policy provided much needed relief to older adults living in poverty, it also created a societal notion that older persons were a homogenous group of aid-deserving individuals. Social Security has come under increased scrutiny as the baby boomer population rapidly approaches retirement. Eligibility for Social Security benefits currently begins at age 65, and there are no economic eligibility requirements. It is estimated that the percentage of the gross domestic product spent on

Social Security will increase by one third over the next 20 years, and that this growth will cause Social Security needs to exceed payroll tax receipts by the year 2012. Policy reform is needed to avoid any potential shortcomings facing the Social Security system over the next decade.

### **Options for Living Arrangements**

Whether it is in age-restricted retirement communities or long-term care, elders, their caregivers, and adult children have more choices than ever before in housing options for this phase of life. The desire to remain independent has brought about an increase in active adult and independent living communities, spurring community-based care services designed to help older adults remain in the community through social support programs, adult day care, home-based care, and other care services. Should more care be required, options range from assisted living—where older adults often have private units similar to apartments and receive nursing, meal, and cleaning services to assist in maintaining a degree of independent living—to long-term care units that offer a place of residence to older adults who can no longer perform activities of daily living and who do not have at-home caregivers to assist them. Secured units help residents with decreased functioning due to dementia live meaningful lives without endangering themselves. In addition, hospice care, an approach to providing comfort and care at life's end rather than heroic lifesaving measures, has become increasingly available via in-home services, specialized units, and hospitals.

### **Psychological Aspects of Aging**

Several developmental theories have been formed to explain the journey from birth to death. Erikson's psychosocial model of development contains stages, each with its own conflict, through which he postulated all individuals progress. His stage for older adults entails the conflict of ego integrity versus despair, where older adults face the task of engaging in life review and gaining peace with past successes and failures, thereby achieving ego integrity. To obtain ego integrity, older adults must accept normal changes in their physical, social, and psychological roles as well as navigate the ageist system in our culture.

The burgeoning field of geropsychology focuses on the mental health of older adults. Unique aspects of

psychosocial challenges for older adults—transitions, grief and loss, increased dependency—are increasingly prevalent. A review of the current literature estimates that mental health disorders among the elderly range from 18% to 28%; estimates are even higher if older adults are institutionalized. The elderly have the highest suicide rate of any group in the United States. However, research indicates that clinical interventions are successful in combating mental disorders such as depression and anxiety in older adults, leading to a clearer understanding that old age does not have to be synonymous with mental disorders or inability to benefit from treatment.

Cognitive changes occur with normal aging, but the majority of older adults are able to preserve their cognitive abilities into later life. In general, thought processes slow, and the incidence of certain types of memory errors increases. Although working memory tends to decline with age, in some cases older adults appear more adept at utilizing both hemispheres of the brain during memory tasks and are able to more successfully regulate emotion for increased memory ability.

For some older adults, cognitive decline surpasses that which is normally expected as individuals age. Dementia, a disease process characterized by several cognitive impairments including problems with memory, is thought to increase with age. This is especially true for dementia of the Alzheimer's type; prevalence rates are as high as 1.6% for individuals ages 65 to 69, and this figure rises to 25% for individuals over 85 years of age.

### **Professional Organizations**

Gerontology continues to be a burgeoning field with opportunities in a multitude of professions. Two of the most recognized professional organizations include the Gerontological Society of America (GSA) and Association for Gerontology in Higher Education (AGHE). These organizations bring together professionals from a variety of disciplines to discuss the most pressing needs of the aged and our changing society.

## HEALTH BELIEF MODEL

---

The Health Belief Model (HBM) was originally developed in the 1950s as a way of understanding apparent resistance to seeking preventive treatment in the form of inoculations and screenings for communicable diseases. It can be described as an organizing framework for predicting acceptance of public and individualized health behavior recommendations. Thus, it appears to have applications in the realms of individual intervention, program development, and public policy. The model focuses on health-related motivation, attempting to define what it takes for an individual to engage in health promoting behaviors. This includes not only engaging in preventive actions, but also following interventions prescribed by various health practitioners. As a value-expectancy theory, HBM examines behavior as a function of the subjective value placed on an outcome and the subjective expectation that the action taken will result in the desired outcome. The model also works from the assumption that good health is valued for most people, focusing on the impact of beliefs and values on health-related decision making.

The model includes four primary variables: perceived susceptibility, perceived severity, perceived benefits, and perceived barriers. Perceived susceptibility addresses an individual's belief of vulnerability to the illness or disease when not experiencing symptoms directly. For individuals who have already been diagnosed, this variable has been adjusted to include their acceptance of the diagnosis as well as their perception of resusceptibility to the illness and general susceptibility in regard to overall health. Perceived

severity entails the perception of how serious individuals believe the potential effects of the illness will be on their lifestyles, including the potential impact on social factors like their ability to work and their family interactions. Susceptibility and severity can be combined to create the construct of *perceived threat*, which in turn can be directly compared to the variable of *perceived benefits*.

The perceived benefits describe an individual's belief in the effectiveness of preventive or prescribed actions. Perceived barriers range from practical issues of money and healthcare access to more psychologically and fear-based issues (i.e., denial, not wanting to know if he or she has a serious illness). Albert Bandura's theory of self-efficacy adds the missing piece to explain the power of perceived barriers in an individual's perception of competence to act in an effective manner to prevent or overcome an illness. In this way, self-efficacy acts as a mediating factor as to whether someone will behave in a health-promoting manner. The model's focus on health-related motivation seems directly related to theories of change, with the four primary variables (i.e., susceptibility, severity, benefits, and barriers) providing a combined understanding of an individual's readiness to act in a health-promoting manner. Higher levels of perceived threat (susceptibility plus severity) combined with strong perceptions of the benefit to action and self-efficacy lead to increased motivation to act in health-promoting ways. HBM has been criticized for not directly accounting for non-health-related motivators for various behaviors (i.e., social acceptance) or economic and environmental factors (i.e., hazardous work environment). However, in breaking down and defining the

primary variables of the model, it seems that these factors may be barriers to action.

### Application of the Model

Applications of HBM extend from the individual to the public policy level. In applying the variables of the model to individual therapy, each can provide insight into the development of an effective intervention that a client will be motivated to carry out. It may also be used in identifying various factors that prevent individuals from successfully reaching health-related therapeutic goals. The identification of barriers has been demonstrated by research to be a primary factor in understanding ineffective treatment regimens. From the larger perspective of public policy and the development of intervention programs, HBM provides a flexible, adaptable model that can be applied to multicultural populations, various illness diagnoses, and preventive health-related actions as well as to a wide variety of approaches to intervention and behavioral outcomes. The four primary constructs can be applied to cultural knowledge regarding a specific population or group in the development of interventions such as breast self-examination and AIDS prevention programs, where the model can enhance the effectiveness of the interventions by disentangling differences in age, gender, and culture in regard to the interaction between the constructs for specific groups. Researchers have pointed out the need to pay close attention to how cultural and socioeconomic factors account for differences in measuring the perception of threat, benefits, and barriers.

### Implications for Future Research

One aspect of HBM that is still not well understood or researched is the concept of cues that stimulate the link between perceptions and actions. Researchers have struggled to identify the complex nature of environmental, interpersonal, and intrapersonal cues. It seems that health-promoting programs could have increased participation and success if the developers of these programs had a more comprehensive understanding of these cues. It is possible that the cues correlate to the interaction between the perceived severity of and the susceptibility to an illness, implying that different cues are necessary for individuals with differing levels of perceived severity and susceptibility. Cues to action (e.g., emotional or social

processes) may be internal (i.e., bodily change or symptom, emotional states, desire to seek approval from a significant other) or external (i.e., media exposure to information, pressure from a loved one to seek treatment). The complexity of measuring the level of influence of these various types of cues continues to challenge researchers in developing studies that would provide information on the impact of such cues on various populations.

The model itself has presented challenges in understanding the specific interactions between the primary variables, self-efficacy, and the predicting behavior. The model suggests that individual perceptions of threat, benefits, and barriers to action may be mediated by self-efficacy beliefs and cues to action that may then predict the likelihood of health-promoting action. Research has demonstrated the individual importance of the primary variables but not necessarily their interaction. Better understanding of the interactions of variables within the model might provide greater power to predict, understand, and enhance participation in preventive health programs as well as in follow-through with respect to prescribed treatment. An example of the dynamic nature of the model is demonstrated by its ability to compare (a) the importance individuals attach to prevention in the context of their own perceived susceptibility to illness versus (b) the importance they attach to benefits of treating an illness they have already contracted.

---

## HIV/AIDS

---

In the early 1980s, an unusual collection of clinical entities appeared that were characterized by aggressive opportunistic infections and malignancies in otherwise healthy individuals. These individuals also demonstrated a severe compromise of immune defense mechanisms. The disease was universally fatal. This complex syndrome of signs and symptoms was labeled as acquired immunodeficiency syndrome (AIDS). Within several years, the agent responsible for the disease (a single-strand RNA virus labeled human immunodeficiency virus, or HIV) was identified by several different research groups. The virus selectively infects a cell line in a person's immune defense mechanism (T-helper cells) that is critical for successful detection of infection, elimination of organisms causing certain infections, or removal of potential tumor cells. HIV, a spectrum disease, progresses in stages. First, shortly after infection, there are mild flu symptoms. This is followed by an asymptomatic phase, which may give rise to symptoms resulting from destruction of the immune defense mechanisms, including opportunistic infections and malignancies (usually within 10 to 15 years). Therefore, a person's ultimate demise is not from HIV per se but instead from the consequences of the ability of the virus to destroy the host's immune defense mechanisms. In all phases of the disease, the same inexorable deterioration of immune system is fueled by HIV.

In the not-too-distant past, a diagnosis of HIV/AIDS in the United States was considered tantamount to death. More recently, however, early diagnosis, aggressive treatment, and the advent of drug combinations have transformed HIV/AIDS into a chronic condition that may afford individuals longevity long after diagnosis. In particular, those who can afford and have access to medications and who adhere to treatment regimens have higher rates of survival than ever before. This increased longevity for HIV/AIDS patients is paralleled by a rise in psychosocial issues related to AIDS survivorship.

It should be considered that while the picture in developed nations is improving with regard to prevention and survival, this is not the case in developing nations or those for whom access to medical care for HIV/AIDS is restricted. Although HIV/AIDS is a disease found throughout the world, there is a very high prevalence in sub-Saharan Africa, and a rapidly increasing prevalence in the Indian subcontinent and the countries making up the former Soviet Union. Moreover, there is a shift occurring in the epidemiology of HIV/AIDS; for example, in the United States the number of AIDS/HIV cases attributable to heterosexual contact with what would be considered non-high-risk partners surpasses the number of cases attributable to heterosexual contact with high-risk partners. Women are becoming increasingly vulnerable in that they account for about 44% of AIDS cases worldwide. In addition, the infection rate for African Americans and Latinos is significantly proportionately higher than the rate for Caucasians in the United States.

For those patients who are fortunate enough to obtain state-of-the-art medical care, however, the resulting increase in longevity has driven the current focus on the importance of the individual's psychological state as a determinant of the success of treatment. Thus, comprehensive treatments for persons with HIV/AIDS include social and psychological services in addition to medical services.

### Risk and Risk Factors for AIDS

HIV can be transmitted between individuals by: (1) engaging in unprotected sex with an HIV-positive partner, (2) injecting drugs using needles contaminated with HIV-infected blood, (3) exposing a fetus at the time of delivery to maternally infected blood, and (4) breast feeding an infant with milk from an HIV infected mother. With effective screening of the blood supply in developed countries, blood transfusion and transplantation of body parts are no longer considered risk factors for HIV; however, this is not universally the case due to the fact that meticulous screening of the blood supply is still not accomplished in developing countries. Healthcare workers who are routinely exposed to blood are also at risk. With the emphasis on the education of healthcare workers, the use of universal precautions, and the introduction of shielded syringes, the risk of needle stick transmission to healthcare workers has dropped to less than 0.03%.

Prevention programs have targeted populations that have a high likelihood of exposure such as individuals who engage in high-risk sexual behaviors and those who are less well educated, are heavy alcohol consumers, are moderate to heavy drug users, or are younger in age, especially teens. Research suggests that heavy alcohol consumption is the factor that is most strongly associated with HIV infection. Also, studies consistently show that between 25% and 35% of people living with HIV/AIDS continue unprotected sexual practices with partners who are HIV negative or who have unknown HIV status.

Research consistently demonstrates that brief, focused behavioral risk-reduction interventions grounded in theoretical models of health behavior change contribute to meaningful reductions in HIV risk behaviors. Support groups reinforce safe sexual practices and positive behavioral changes and may use educational and skill-building techniques. Attrition is a difficult challenge with prevention groups, and although individual or small group interventions are shown to be most effective, they are often difficult to implement in public health settings.

### Diagnosis of HIV/AIDS

The medical conditions associated with HIV disease that may indicate infection often depend upon the region in which the patient is diagnosed. In developing countries, infection with mycobacterium tuberculosis, severe and frequent gastroenteritis with subsequent malnutrition, and respiratory infections are frequently life defining.

On the other hand, in developed countries, opportunistic infections such as *Pneumocystis carinii* pneumonia, toxoplasmosis, repeated bacterial pneumonia, lymphoma, disseminated fungal infections, and Kaposi sarcoma are conditions suggesting underlying HIV infection. Death is the result of an immune system so weakened that, even with appropriate therapeutic agents, there is no inherent mechanism to mount a successful host defense.

There are a number of issues involved in testing for HIV that have psychosocial implications. First, patients must confront identifying themselves as at risk for a disease that is socially stigmatizing; they must face the fear of disclosure. Second, there is a waiting period between being tested and finding out the results. Finally, there is the process of coping with the

social and personal implications of an HIV-positive diagnosis. A further complication for health care is that between 9% and 28% of those patients tested do not return for the results of the testing.

When informed of HIV-positive status, many patients experience an increase in anxiety, depression, and general psychological distress. Those who receive stress management treatment prior to knowing if they are infected, however, showed significantly less increase in depression and no increase in anxiety compared to controls.

Following an HIV-positive diagnosis, there may be an asymptomatic period that can last for many years. Several studies have shown that anxiety and depression during this time is in the normal range, although differences do appear after the diagnosis of AIDS (with significant symptomatology). In the vocational, domestic, sexual, and social domains of psychosocial adjustment, men with AIDS are more poorly adjusted than uninfected men and HIV-positive asymptomatic men, who are similar to one another. Moreover, there is some evidence that men with HIV who are depressed when they are asymptomatic may have an overall greater immune system impairment (e.g., CD4 lymphocyte decrement) over time (6 years) than those who were not depressed. Thus, the early diagnosis and treatment of depression might be important for the subsequent well-being of the HIV-positive person.

### Progress in Medical Treatment

Each treatment for AIDS has a unique impact on the coping process. Therapeutic options to treat HIV rather than only the consequences of immune system suppression started in 1987 with the advent of AZT, a medicine that interfered with the life cycle of HIV in the host T-helper cell. The effectiveness of the medicine was usually short lived because of the ability of HIV to mutate and because agents operating at multiple sites of the virus replication were not yet available. A breakthrough in treatment occurred in 1996 when highly aggressive antiretroviral therapy (HAART) became a reality.

Drugs that interfere at three different sites of HIV replication were now available, and the dramatic drop in the annual rate of death from HIV throughout the United States was remarkable. The development of drugs to interfere at other locations in the viral life cycle continues. Additionally, there is significant

drive to reach the elusive goal of developing an effective vaccine to assist the infected host to limit viral replication. Finally, the adherence to treatment regimens has been markedly simplified from 28 pills per day in 1996 to 2 in 2004. Furthermore, the Food and Drug Administration (FDA) just approved a one-pill-per-day regimen, which represents a cooperative effort among several drug companies.

### Psychological Coping

The term *coping* is often used with AIDS in that the disease is conceived of as a threat that may tax the resources of the individual. Men with AIDS who use avoidant coping strategies experience more psychological distress than those who used social support or active-behavioral approaches to problem solving. Also, avoidant coping is associated with higher levels of depression, more health concerns, lower levels of social support, and lower self-esteem compared to active-behavioral coping. A belief in personal control that relates to day-to-day symptoms and to the overall course of the illness were associated with positive adjustment to AIDS. Thus, men who adjust well to AIDS view themselves not as passive victims of the disease but as having control over certain daily aspects of the disease and the overall course of the disease.

### Social Support

The stigmatizing aspects of HIV/AIDS are often accompanied by the fear of loss of social support. Moreover, symptoms may impact social support. The greater the number of physical symptoms reported by a person with AIDS, the less social support is perceived to be available and the greater the concomitant depression and anxiety. Researchers suggest that two processes may operate: First, serious illness may alter the support network significantly, and second, stigmatizing disease such as AIDS may be associated with decreased social support, which may be accompanied by withdrawal by the person with AIDS to avoid future rejection. Reports of higher levels of social support were associated with lower levels of hopelessness and depression, but the latter constructs were not correlated with physical symptoms, suggesting that suicidal ideation may be related more to the loss of support than to the state of the disease. Persons with AIDS who perceived an increase in

social support and those who perceived no loss in support adjusted better than persons who perceived a loss in social support.

### Quality of Life

It has been estimated that individuals with AIDS spend several hours each day on personal medical care, paperwork, getting the extra rest needed to sustain activity, and other activities relating to self-care, which would suggest that quality of life plays a large role in the life of a person with AIDS. HIV/AIDS carries with it the burden of personal health issues that are very time consuming and the social burden of being stigmatized. Thus, quality of life may be affected by both the disease and the social stigma attached to it.

### Long-Term Survivors of AIDS

The Centers for Disease Control and Prevention (CDC) define long-term survival as survival 3 years after diagnosis. Not only has the survival rate doubled in the past decade, but with the advent of HAART the survival rate should increase even more dramatically over the next 10 years. Much of the research in this realm is descriptive but seems to indicate that survivors most often have active coping styles and are relatively free of mood disorders and other psychological distress. In addition, most long-term survivors have had bouts with life-threatening illness and seemed to bounce back after each setback. Moreover, survivors tend to believe that they will experience good times and feel strongly that their lives are important.

Long-term survivors support the use of traditional medicine, particularly to treat opportunistic infection. They are also more likely to believe that chance or personal control are associated with health outcomes rather than the actions of powerful others. That is, they tend to believe that medical interventions can help but are not a panacea. There is very little, if any, use of denial as a coping strategy in long-term survivors. Moreover, there is flexible use of many different types of active coping strategies.

Given that more adults are being infected at later ages, and due to the increased effectiveness of the medical management of HIV/AIDS, there are a number of older persons living with HIV/AIDS. This new phenomenon has both medical and psychological implications. Research suggests that middle-aged and

older persons living with the disease experience significant emotional distress and thoughts of suicide. This particular population may have unique psychological concerns, and they are likely to approach such issues differently than younger persons with HIV/AIDS. Thus, interventions should be tailored to reflect the developmental contexts.

### Psychosocial Interventions to Promote Quality of Life and Longevity

Recommendations have been made concerning the psychosocial needs of AIDS survivors. Essentially, the recommendations include the need to support the survivors' tendency to engage in active coping that is powered by beliefs of personal control. Also, therapists should be mindful of changes in the support network of the person with AIDS. A shrinking social network may portend a less than optimistic outlook for long-term survival.

Research on psychosocial interventions to enhance quality of life has shown great promise for enhancing coping. One approach, which includes a cognitive-behavioral stress management treatment, focuses on recognizing the signs of stress and negative automatic thoughts, relaxation training, and providing information on AIDS and the immune system, sexual risk behaviors, and social support. The stress management and information sessions are alternated with relaxation sessions. This treatment resulted in reduced anxiety and depression for HIV-positive males as compared to a no-treatment control group whose members also had decreased immunological functioning after notification of the results of HIV testing. At 1-year follow-up, coping strategies such as denial and disengagement were associated with increased depression. On the other hand, coping skills such as active coping, planning, and positive reappraisal were associated with a decrease in depressive symptoms. At 2-year follow-up, predictors of disease progression included degree of distress at time of diagnosis, denial, poor attendance in the group, and failure to comply with relaxation homework. Thus, the functional status of men who did not use denial and who participated fully in the intervention was better than those who used denial and who did not adhere to the treatment protocol. In sum, psychological interventions for persons with cancer and HIV have beneficial effects on psychosocial functioning, quality of life, and survival in the case of cancer. Common components of these interventions

include group support, fear reduction, problem solving, and stress management.

## HOMELESS YOUTH

---

Youth homelessness is a complex problem exacerbated by the lack of available information regarding the unique circumstances experienced by these adolescents and further by the fact that this population is often hidden and therefore unnoticed by the general public and researchers. In any given year in the United States, 500,000 to 1.5 million youth will run away or be told to leave their homes. Most runaways return home, but others go on to establish an intermittent or prolonged period of homelessness. The number of homeless youth is difficult to estimate, but one national survey found that 7.6% of youth (1.6 million) between the ages of 12 and 17 were homeless, with approximately 200,000 of these individuals living on the street. Regardless of the exact number, youth homelessness is a cause for concern because of the unfavorable outcomes many of these youth experience: heightened risk of involvement in delinquent activities, drug and/or alcohol abuse, and persistent homelessness hindering their ability to become productive community members or successful adults. Furthermore, information regarding youth who do not survive is scarce.

Community agencies dedicated to assisting homeless persons frequently contribute to what is known

about this population. However, information from this source may overlook a substantial portion of homeless youth given that many choose not to access these resources. Moreover, youth with the most significant challenges can be rejected from such facilities due to histories of substance abuse or psychosocial troubles. Little is known about treatment needs or effective intervention strategies for these adolescents, because research efforts have primarily focused attention on the circumstances that contribute to a youth's decision to leave home. Knowledge about these variables may have implications for prevention efforts, but it is complicated by the variety of reasons adolescents choose to leave home. It is important to note that although some youth may be homeless along with their families, due to financial reasons, the focus of this entry is on youth who are separated from their families.

### Causes of Homelessness in Youth

Homeless youth typically reside in unsafe living conditions that differ greatly from those of their peers both before and after leaving home. The home environment is generally characterized by dysfunctional experiences such as abuse, neglect, exploitation, rigid or inconsistent disciplinary practices, conflict, and parental substance abuse. Youth living in these homes experience a diminished sense of control and decreased self-esteem. In addition to unsafe home environments, many youth have encountered numerous, inconsistent living arrangements in alternative care settings by the time they reach the streets. As a result of these and other compounding adverse experiences, homeless adolescents commonly display many mental health and behavioral problems even before they leave home. These problems may be further compounded by discouraging educational experiences such as underachievement, inconsistent attendance, grade retention, poor relationships with peers and teachers, and disciplinary actions.

### Defining Homeless Youth

Although all of these adolescents can be classified under the term *homeless youth*, several other terms have been used to describe the conditions surrounding a youth's choice (or lack of choice) in leaving home and the unique circumstances the youth encounters while away from home. These distinctions are important, as they define intervention strategies that will be most appropriate for an individual's circumstances. For example, youth who have been asked or forced to leave

home or abandoned by their parents are typically classified as *throwaways*. Youth commonly associated with this category are those whose sexual orientation does not align with their parents' expectations. Gay, lesbian, bisexual, transgender, and questioning (GLBTQ) adolescents represent a significant portion of youth who are asked or forced to leave their home setting. In this circumstance, seeking reunification with a family may not be an appropriate therapeutic goal.

Adolescents who leave home without parental consent or knowledge are termed *runaways* and may exhibit different patterns of runaway behaviors. A *chronic runaway* may demonstrate a pattern of leaving and returning home several times over a period of time while an *acute runaway* is described as an individual who has a single episode of leaving home and staying away for a significant length of time, resulting in the youth returning home for good or never returning at all. These families may be more appropriate for family-focused interventions such as multidimensional family therapy (MDFT) that emphasizes the use of multiple therapeutic models to reduce high-risk behavior and substance abuse in adolescents.

Once youth leave home, they pursue distinctive paths in an effort to survive. Homeless youth tend to reside in one of three environments: the street, shelters, or the system. Youth who live on the streets may or may not maintain contact with their families. For example, some may return home after short periods of working or living on the street, whereas other homeless youth identify the street as their home and have little, if any, contact with their families. These youth commonly have acute mental health difficulties and more significant histories of homelessness than other categories of homeless youth. Additionally, they are less likely to access available community resources. Conversely, there are homeless youth who mainly reside at homeless or emergency shelters and may have no experiences on the streets, similar to those youth who spend a majority of their time residing in alternative care settings such as foster homes, emergency shelters, or juvenile detention centers.

### Risks of Youth Homelessness

Regardless of the location where homeless youth reside, all are at significant risk of unfavorable developmental outcomes. Survival mechanisms, sometimes valued as street skills, employed by homeless youth often place them at increased risk for a host of deleterious consequences. These adolescents lack adult

guidance and support as well as other basic needs such as food, shelter, and health care. Many homeless youth suffer drug and alcohol addictions and may be involved in distribution for monetary gain or in exchange for material needs. Others may engage in prostitution or survival sex, defined as sexual favors exchanged to get basic needs met. Such practices place youth at risk of sexually transmitted diseases, victimization, and exploitation. Activities viewed by mainstream society as delinquent or criminal are often used by homeless youth as a means of survival. In addition to panhandling, various degrees of stealing such as shoplifting, swindling, or pickpocketing may be utilized. The contradictory norms of the general culture and the street culture may contribute to the difficulty these youth experience when attempting to reintegrate into society.

At the most basic level, homeless youth experience poor nutrition, limited access to health care, and unsafe living conditions, which place many at risk for illness, infections, and diseases. In addition to physical harm, they commonly experience multiple mental health problems, many of which were present prior to leaving home and are intensified once on the streets. Many homeless youth have endured significant abuse and assault from trusted authority figures, either at home or while away from home, making it difficult for them to trust others. Fear, loneliness, and feelings of worthlessness are also common amongst this group. Depression and suicidal ideation are maintained due to minimal encouraging experiences.

### Interventions for Homeless Youth

The current literature regarding empirically based interventions for use with homeless adolescents is insufficient. Given that much of the available information addresses the behaviors the youth exhibited and the experiences he or she had prior to leaving home, an appropriate area of focus should be directed toward prevention of youth homelessness. Prevention approaches might include connecting the family to needed resources, family-focused therapy (e.g., MDFT or multisystemic family therapy) for those at high risk, and wraparound services for the youth and family. Because of the complexity of the issues that lead to youth homelessness, it is unrealistic to expect that any unidimensional approach will be sufficient to improve family and youth functioning. A systemic model is needed to more completely address the needs of these youth and their families.

Prevention is critical, because once youth have left home, it is difficult for service agencies to gain access to these adolescents. Few homeless youth choose to approach community resources because of fear and mistrust of adults, lack of willingness to follow the rules associated with an agency, or lack of knowledge of the resources that exist. Therefore, when counseling does occur, it is typically involuntary and tends to be the result of a referral for family therapy by social or shelter services, or it is court ordered for the youth and his or her family. Reuniting young people with their families may seem the most reasonable intervention; however, in some instances this may produce harmful results rather than benefiting the youth. Therefore, it is important to carefully evaluate the reasons why the youth left home and the current family environment before establishing reunification as a goal.

When youth voluntarily access services either for general or for mental health support, there remain a number of barriers that might make effective service provision difficult. Lack of control and constant unsuccessful experiences with adult figures frequently interfere with the ability of these youth to trust others and may result in heightened expressions of resistance. Furthermore, the high mobility rate among this population presents limitations to building a trusting relationship. It has been suggested that the most effective services will be those that are brought to the youth (e.g., parks, urban settings) to facilitate access. Those who provide services need to consider their approach, as coming on too strong might scare youth, yet an approach that is too reserved might inadvertently reinforce the idea that adults do not care. It has also been noted that services should be culturally compatible; that is, the provider should be respectful and understanding of youth and their circumstances. It is important to reinforce the youths' sense of control and choice (as appropriate) and minimize restrictions and requirements. Developmentally, these youth may need to work toward establishing a sense of identity, feelings of competency, and connectedness to others. The therapeutic relationship may also include life skills education such as safe sexual practices, needle exchange, and other mechanisms by which to stay safe.

Because some youth grow tired of living on the street, programs that focus on helping youth reintegrate into society may be appropriate. In doing so, it is critical that youth are taught the skills they need to be successful and reduce the chances of further rejection and disapproval, which might increase their risk

for continued homelessness. One program, *First Voice*, was originally designed to help adolescents in foster care transition to independent living as adults. Its emphasis on independence, belonging, mastery, and generosity (after the circle of courage model) may represent a useful approach for transitioning youth from street or shelter environments to becoming productive community members.

## HOSPICE

---

Hospice is a multidisciplinary approach to caring for individuals who have a terminal illness or condition. It is based on a philosophy that affirms life and advocates self-determination. The family is considered the unit of

care and the hospice team of professionals provides medical, emotional, and spiritual assistance to patients as well as to their families and friends. Typically a team includes physicians, nurses, chaplains, social workers, counselors, nursing assistants, holistic practitioners, trained volunteers, and administrative and clerical staff. Services may be provided in an inpatient setting, long-term care facility, or the patient's home.

### History

The word *hospice* is derived from the Latin *hospitium*, an inn for travelers usually maintained by members of a religious order. Jeanne Garnier, founder of the Dames de Calaire in Lyon, France, first used the name with reference to the care of dying patients in 1842. In 1879 the Irish Sisters of Charity opened Our Lady's Hospice in Dublin, and in 1905 they established St. Joseph's Hospice in London. The founder of the modern hospice movement was Cicely Saunders, a physician, who started St. Christopher's Hospice in London in 1967. She was inspired by a patient, David Tasma, with inoperable cancer. The two discussed how the care of dying patients might best be done in a setting specifically created for it, and when Tasma died, he left Saunders money to establish such a place. During the next several years the hospice concept spread throughout the world. In 1974, hospice care was introduced in the United States at Yale University in New Haven, Connecticut.

### Administration and Funding

#### Types

Hospice services are provided in a variety of settings and have multiple avenues of funding. They may be part of a home health agency, have a freestanding facility or space in a local hospital, or be provided to patients in their homes or wherever they may be staying. Hospices may rarely be staffed by volunteers but are usually operated by paid specialists.

#### Admission

To be admitted to a hospice program, a patient must obtain a physician's order. This order can be requested by anyone, including the patient, a family member, or a health-care provider. Any physician can write such an order as long as it states that in the physician's best

medical judgment, the patient has 6 months or less to live, regardless of age or diagnosis. Hospice care will be continued as long as the patient lives, provided a progressive decline can be demonstrated.

### ***Funding***

Once admitted to the hospice program, most patients are eligible for funding under the Hospice Medicare benefit, which does not depend on age. Patients may qualify for other financial resources, such as Medicaid. Hospices also receive funding from grants and donations, fundraising activities, and other state, local, or federal sources. Most hospices have a policy of providing service to those in need even if the usual avenues of reimbursement are not available. Besides those already mentioned, such services typically include paying for any medications related to the patient's diagnosis and providing needed equipment, such as oxygen delivery systems, wheelchairs, hospital beds, and similar supplies.

## **The Hospice Philosophy**

### ***Affirmation of Life***

Hospice philosophy involves affirming and respecting life and honoring death as a natural part of existence. The policy of the National Hospice Association is that hospice does not hasten death or prolong life. The aim of hospice services is to maximize the *quality* of whatever time may remain for every patient and for their families and friends. Hospice nurses are experts in symptom management, particularly pain control, and this knowledge is used to promote patient comfort. Social workers and bereavement counselors assist patients and families with the psychological and emotional factors that may accompany the dying process. Chaplains honor all spiritual and religious beliefs, and can facilitate the attainment of peace and faith at this stage of life. Ancillary personnel, such as nursing assistants, volunteers, and alternative therapists also have as their aim helping the patient and family live a full and comfortable life.

### ***Self-Determination***

Part of honoring life is the acknowledgment that each patient is an individual and has unique values, preferences, and desires. Hospice believes that the

patient and family have the right to make decisions about the types of services they receive and the general management of their care. Hospice team members offer information to assist with these decisions, and can facilitate the decision-making process, but they do not choose which course of action the patient will take. Research has shown that being able to make choices is one of the most empowering things a patient can do. Patients are often distressed if they lose the physical and mental abilities that used to come so easily. But if they are encouraged to continue to make as many decisions as possible about their care, they are able to maintain a sense of control and competence.

## **Psychological Aspects of Hospice Care**

Psychological support provided by hospices generally includes care offered to the patient and family prior to the patient's death, bereavement services after the death, and emergency response and outreach to the local community. During the patient's life, medical social workers assist the patient and family with emotional, financial, legal, ethical, and other concerns that often arise during the last stage of life. Following the patient's death, bereavement specialists, who may be social workers, psychotherapists, counselors, or other professionals, assist family and friends with grief support services. Hospice social workers and counselors may also respond to community crises, such as the death of a student, which may affect large numbers of people.

### ***Psychological Services During the Patient's Life***

When a patient is admitted to hospice care, a medical social worker (MSW) meets with the family to conduct an initial psychosocial assessment. This is an opportunity to become acquainted with the patient, identify particular needs, and evaluate family functioning to highlight strengths as well as possible areas of concern. The MSW does not attempt to radically restructure long-standing family dynamics but instead attempts to maximize the effectiveness of the family's existing coping strategies. Information about living wills and other practical matters is also provided.

Hospice staff use a variety of theoretical approaches, depending on each therapist's orientation and the needs of the family. For example, a person-centered approach may be appropriate as patients and families

relate their history and express feelings about their situation. For individuals seeking to modify distressing thought patterns, a cognitive-behavioral approach might be used.

While every situation is different, most patients and families experience similar feelings and challenges during a terminal illness or condition. The MSW can support the family by normalizing these common occurrences and reassuring clients that they are not abnormal or crazy.

For example, educating families about Elisabeth Kübler Ross's stages of grief can help them understand the emotional turmoil they may be experiencing. Research indicates that individuals are often quite relieved to learn that denial, anger, bargaining, depression, and acceptance are normal aspects of the dying process and can be experienced in various degrees and sequences. The MSW may also suggest strategies for dealing with each of these stages.

Anticipatory grief has long been a phenomenon commonly noted in hospice clients. Mourning may begin as soon as the probable outcome of the patient's condition is known. This may involve increased anxiety, role rehearsal by the survivors, emotional withdrawal of the patient or survivors, and extreme emotional attachment to the patient. The MSW can facilitate understanding and management of these occurrences. Recently, research by Robert Fulton and others suggests that anticipatory grief may be a social construct and its practical and theoretical validity is being explored.

Caregiver stress is another area commonly addressed by the hospice social worker. The physical and emotional manifestations of caring for a terminally ill patient can include exhaustion, feelings of being overwhelmed, guilt, regret, anger, and anxiety. The MSW can suggest stress management techniques and explore other avenues of relief, such as respite care for the patient and volunteers to assist with household tasks or sit with the patient while the caregiver takes a break. Caregiver support groups provide an opportunity to share experiences and coping strategies.

### ***Psychological Services After the Patient's Death***

After a hospice patient dies, grieving survivors often experience a variety of emotional, physical, spiritual, and behavioral distress. The bereavement staff will continue to provide services to family and friends as long as necessary. These are essentially the

same as predeath interventions, with emphasis on the grief process. They include individual and group therapy, reading lists and other similar resources, education, and referral to other mental health practitioners when necessary. Additional techniques for children include the use of sand play therapy, puppets, and animal-assisted therapy.

### ***Community Outreach***

Hospice social workers and counselors also respond to community emergencies when needed. The trauma of natural disasters and the grief experienced by children when a classmate dies are examples of situations where the expertise of hospice professionals may be utilized.

## **Ethical Aspects of Hospice Care**

Withdrawal of advanced life support and the concept of assisted suicide present challenges in caring for hospice patients. Technological advances in acute care make it possible to keep patients alive artificially for extended periods. Hospice workers emphasize the importance of having a living will that specifies the patient's wishes regarding the artificial prolonging of life. This can eliminate the conflict that may arise as the patient declines.

The official stance of the National Hospice Organization is that assisted suicide is not part of the hospice philosophy. However, patients not infrequently ask hospice workers to help them die. Theresa Harvath and others address the personal and professional issues that may arise in this difficult situation. Hospice staff assess and treat any physical symptoms that may contribute to suicidal ideation and encourage the patient to explore unresolved psychological and spiritual issues.

## HUMAN SUBJECTS REVIEW IN AN ONLINE WORLD

---

The World Wide Web has had a substantial impact on research methodology in counseling psychology and in the social and behavioral sciences in general. Indeed, the Internet offers opportunities for research in content areas where traditional methodologies have struggled and special samples have previously been difficult to recruit. However, the Internet also presents many challenges for the ethical conduct of research involving human subjects.

There are two primary types of research utilizing the Internet: online survey research and observational research. Online surveys, created by either the researcher or outside agencies, allow researchers to collect self-report data via an Internet Web page as opposed to more conventional methods (e.g., in person, via mail). Observational research involving chat rooms and discussion boards on the Internet is

the second type; here researchers monitor the social behavior of online groups by examining current or archived written communications (e.g., e-mails). Online data collection has several potential benefits to the researcher, including the possibility of collecting data from respondents across geographical and cultural boundaries, access to specialized or difficult-to-find populations, reduced time spent in collecting data, and decreased cost for discussion.

There is a third, emerging research use of the Internet that involves the delivery and evaluation of therapeutic interventions. Besides the ethical considerations shared with other types of online research, this type presents some additional challenges. (For a discussion of the ethical issues surrounding online therapeutic interventions, see Childress & Asamen, 1998).

This entry presents a general overview of guidelines for protection of human subjects in research as well as a description of the Institutional Review Board (IRB) criteria for work with human subjects that are most critical for evaluating online research. Then it outlines the criteria used by IRBs with respect to the main types of online research.

### General Ethical Guidelines

The Belmont Report, by the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, presents the basic principles to guide ethical scientific research. The principles put forth in the Belmont Report allow for the weighing of costs or risks to human subjects and the benefits of conducting the research. These principles of *respect for persons*, *beneficence*, and *justice* have been standardized into the federal policy for the Protection of Human Subjects, or the *Common Rule* (Code of Federal Regulations, <http://www.hhs.gov/ohrp/humansubjects/guidance/45cfr46.htm>). The Common Rule established the IRB system to assist those conducting research to comply with the regulation.

The IRB at each college, university, agency, or private research company has its own interpretation of particular policies and procedures regarding human subject protection, but there is a set of criteria common across each IRB. To be considered protective of human subjects, the proposed research should (1) minimize risk to participants, (2) present a favorable benefit/cost ratio, (3) ensure equitable selection of participants, (4) provide informed consent to all participants, and (5) document informed consent.

These goals reflect the principles of *respect for persons* or *autonomy* (i.e., providing and documenting informed consent), *beneficence* (i.e., minimizing risk to participants, presenting a favorable benefit/cost ratio) and *justice* (i.e., equitable selection of participants) put forth in the Belmont Report.

### **Ethical Issues Related to Autonomy for Online Research**

Appropriate documentation of voluntary informed consent from research participants is a requirement of IRBs. However, ensuring understanding of research procedures and obtaining signatures through the Internet presents a challenge to researchers. IRBs have the option to waive this requirement if the research involves minimal risk to the participant or in cases where the documentation would be the only link between the participant and his or her data. Thus, some IRBs have indicated that simply completing the online survey signifies consent to participate.

Of course, the challenge of ensuring understanding is not unique to online research. One study by Varnhagen and colleagues compared the recall of online consent forms to regular paper format versions. Little difference in recall was found between participants who viewed the online version and those who received the paper version. However, on average, participants' recall was quite low across conditions, with participants recalling less than 10% of presented material. This suggests that researchers need to make every effort to attract participants' attention to the information about the study in the consent document.

### **Ethical Issues Related to Beneficence for Online Research**

A primary aim of IRBs is to ensure that researchers minimize the risks to research participants. Two potential sources of risk exist: harm resulting from a breach of confidentiality and harm resulting from direct participation in research. Online research raises several concerns regarding privacy, anonymity, and confidentiality. Discussion of ethical issues on the Internet has focused on whether or not the Internet, and the information posted therein, lies in the public or the private domain. When online behavior is considered public, a research project examining this behavior is considered in the "exempt" category, though it still must receive review and approval from

an IRB. However, chat rooms and bulletin boards may lead an individual to develop an expectation of privacy when, for example, an account and password are required to access the site. This expectation of privacy needs to be considered before conducting research utilizing such sites. Indeed, some have recommended that IRBs evaluate the public versus private nature of each project on a case-by-case basis.

A concern associated with direct participation in online research is data security. According to Im and Chee, online data collection raises the possibility that data may be viewed by others unbeknownst to the researcher. For example, employers may have access to their employees' Internet history and e-mail account, and hackers may attempt to discover individuals' personal information. Researchers should be able to articulate and demonstrate that the data are collected, stored, and transmitted in a way that maintains confidentiality. The more sensitive the data collected, the greater the precautions that should be taken to ensure the protection of this information.

### **Ethical Issues Related to Justice for Online Research**

A touted benefit of online research is the potential for the recruitment of large, diverse samples. However, researchers need to be aware that samples may not represent an equitable selection of potential participants. In fact, researchers may be unintentionally excluding particular groups of people from the research. For example, individuals who cannot be identified via the Internet, who are illiterate, or who are not fluent in the language used in the online survey or on the Web page discussion board may be excluded. Further, researchers have noted the presence of educational, economic, racial, and gender disparities among those who have access to the Internet—the so-called digital divide. There is evidence, however, that these differences are diminishing. In any case, researchers need to provide evidence to IRBs that they are making their best effort to recruit samples that give the most individuals an opportunity for selection.

hypnosis and specific hypnotic techniques with a client within an established therapeutic relationship prior to undertaking such procedures. Historically, hypnosis has been viewed with wariness and a fear that one may acquiesce to the commands of the hypnotist and lose control both cognitively and physically. A thorough explanation of the procedures to be used and their purposes can serve to allay these concerns.

Similar to a very deep state of relaxation, hypnosis is an altered state of consciousness. The hypnotized client has a more focused awareness and is open to suggestion or direction by the therapist. Various approaches within hypnosis exist. For example, a therapist might use hypnosis to help a client visualize how to achieve a particular goal; a therapist might also use hypnosis to stimulate vivid images and thereby achieve a focused state of relaxation or expectation. For counseling clients with health-related concerns (e.g., chronic pain), hypnosis appears to be a positive adjunct to ongoing coping skills treatment.

Individual experiences of the hypnotic state appear to vary from person to person. However, positive expectations and comfort of both the clinician and the client affect the likelihood of inducing trance and enhancing suggestibility. Therefore, it becomes important that the hypnotist have the knowledge and experience to create a trusting environment in which the client anticipates success. In addition, the ethical use of hypnotic techniques requires training and supervised application to assure that the clinician is practicing within the bounds of her or his expertise.

Currently, hypnosis is most often used therapeutically in combination with more extensive theoretical approaches and treatment strategies in clinical practice.

## HYPNOSIS

---

While it is difficult to describe the nature of hypnosis scientifically, procedurally a therapist induces a trance, or deeply relaxed state, in a person through the means of suggestion of alterations of sensations, consciousness, and cognitions. As with the broader field of psychotherapy, there is an array of historical, theoretical, and technical assumptions that constitute the underpinnings of clinical hypnosis that are far too extensive for the scope of this entry.

Clients differ in their beliefs, needs, and goals; thus, it is important to explore the usefulness and risks of

## IMPAIRMENT

---

Impairment is the inability to practice in congruence with professionally defined and accepted standards of care. Impairment among trainees and professionals is a problem within psychology and counseling. Surveys have revealed that up to 10% of professional psychologists reported difficulties with depression, alcohol and other substances, relationship problems, and physical illnesses, all of which significantly interfered with their carrying out their responsibilities with their usual level of skill and ability.

Ethical codes of counselors and psychologists mandate that professionals practice with the highest levels of care and obtain supervision or intervention when their own concerns and difficulties interfere with meeting this standard set by the codes. It is important to distinguish between *distress* and *impairment* in considering the topic of impairment. Many psychologists and counselors experience difficulties in their own lives that, while distressing, are not of sufficient impact to negatively affect their work. Impairment, however, typically denotes a significant level of distress that interferes with the ability to competently care for clients, complete necessary and appropriate documentation, and so on. Individuals who are impaired may not recognize that their difficulties are causing interference. And finally, impaired therapists may engage in inappropriate or unethical behavior with clients (e.g., dual relationships, sexual relationships) or supervisees.

O'Connor presented data that suggested mental health professionals may have experienced developmental trauma that was unresolved prior to taking on

their caring roles. In his review of this issue, he cited research that indicated between 33% and 50% of psychologists reported alcoholism, physical abuse, or sexual abuse in their family of origin. While a traumatic childhood experience, if resolved, would allow a therapist to more fully identify with similarly treated clients, it also raises the possibility of countertransference issues, problems in separating from clients, substance abuse, and underestimation of the impact of one's own history on work with clients.

Unfortunately, psychology and counseling professions have had difficulty in identifying impairment as a professional issue. Other professions, such as medicine, dentistry, and nursing, have more fully developed impairment programs that encourage self-identification, supervised remediation, and continued practice and treatment. Additionally, psychologists in general are apt to see more egregious ethical violations, such as sexual relationships with clients, as something they would "never do." Yet, under the right circumstances, any therapist can be vulnerable to personal conditions that promote the likelihood of ethical violations or boundary crossings.

Psychology tends to intervene after the fact, after a client or colleague has filed an ethical charge, and then a disciplinary focus takes over in a licensing board or ethics committee approach to adjudicating the case. This is in contrast to professions mentioned above where diversion, monitoring, and supervision are used as opposed to disciplinary hearings and delicensing outcomes.

Detecting impairment during training is the most effective approach to preventing impaired professionals. Yet, as Lamb notes, identifying and responding to

trainees who show evidence of impairment is problematic. In part this difficulty lies in supervisors being insufficiently trained to detect impairment; in part, training programs have not developed policies with which to approach the problem of impaired trainees. It is during training, however, that the three component parts of impairment are most likely to reveal themselves in trainees: an inability or an unwillingness to integrate professional standards into one's own behaviors, an inability to acquire professional skills to reach an acceptable level of competence, and an inability to manage personal stressors and the resulting emotional and behavioral dysfunctions.

Program faculty and supervisors are in the best position to be proactive regarding impairment issues, but the professional community at large also needs to be involved in developing improved methods for detecting and treating impairment.

## INDIVIDUALS WITH DISABILITIES EDUCATION ACT

The Individuals with Disabilities Education Act (IDEA) is a federal law that ensures that all children ages birth through 21 receive a free and appropriate public school education regardless of the severity or type of their disability. Before this law was passed, many children with disabilities were excluded entirely from participation in public education or were not receiving an education appropriately designed to meet their needs.

Originally introduced into legislation in 1975 as the Education of All Handicapped Children Act (Public Law No. 94-142), the law was renamed in 1990 and has since undergone two additional reauthorizations. President George W. Bush signed the most recent reauthorization into law on December 3, 2004, and most provisions became effective on July 1, 2005. Final regulations were made available on August 14, 2006. This reauthorization was characterized by several modifications, including revised and added definitions, revised school discipline procedures, an emphasis on progress monitoring and accountability, changes to procedures in funding allocation, and changes intended to better align the act with the No Child Left Behind act. In addition, taking into consideration feedback from several national organizations and the public, the authors included measures to support the needs of at-risk populations, including homeless children and their families, migratory families, children with limited English proficiency, children exposed to family violence, and children in foster care.

Like its predecessors, the revised IDEA outlines state and local education agency responsibilities, procedures and criteria for determining eligibility for services, regulations pertaining to documentation and monitoring of services and student progress, the scope of included services and placements, and safeguards related to parental involvement and privacy. The law is divided into four parts. Part A outlines general provisions. Children ages 3 through 21 are covered under Part B. Part C details unique regulations concerning services for infants and toddlers with disabilities. Part D includes a description of national activities to improve the education of children with disabilities. IDEA also details the provision of funding to local and state agencies that serve children with disabilities in accordance with this law. IDEA is not fully funded

and does not cover all expenses incurred by schools to provide services to individuals with disabilities.

### Role of Mental Health Providers

IDEA groups mental health providers, including counselors, psychologists, social workers, and rehabilitation counselors, under the general umbrella of “related services.” Specifically, related services are defined by IDEA as those services necessary to assist a child with a disability to benefit from special education. IDEA broadly paints the scope of mental health services, indicating that related service providers may be involved in any of the following: direct counseling with students, early identification and assessment of disabilities, social work services, and parent counseling and training. Practitioners may also be responsible for linking school-based services with outside community resources such as primary care physicians, juvenile justice systems, child welfare agencies, and public recreation agencies. The newest revision of IDEA emphasizes the role of mental health providers in creating a safe school environment as indicated by the explicit description of counselors’ role in implementing and monitoring individual and systemwide positive behavioral interventions. School-based mental health practitioners are also likely to participate in disciplinary decisions and should be familiar with revised IDEA regulations pertaining to disciplinary actions with students with disabilities. The revised guidelines explicitly describe procedures for determining whether the conduct of a child with a disability is a manifestation of his or her disability, and they include criteria for determining when a functional behavior assessment and behavior intervention plan must be implemented.

### Assessment and Eligibility Issues

IDEA defines children eligible for services based on whether or not they have a disability outlined in 13 categories, including mental retardation, hearing impairment (including deafness), speech or language impairment, visual impairment (including blindness), emotional disturbance, orthopedic impairment, autism, traumatic brain injury, other health impairment, specific learning disability, deaf-blindness, or multiple disabilities. Practitioners working in schools should familiarize themselves with both the federal definitions outlined in IDEA and their state’s interpretation of these disability categories.

These categories overlap with diagnostic codes of the *Diagnostic and Statistical Manual of Mental Disorder, Fourth Edition, Text Revision (DSM-IV-TR)* but are also markedly different. Practitioners familiar with *DSM-IV-TR* diagnostic criteria will notice that several childhood disorders are not overtly represented in these eligibility criteria. However, these children may qualify for services under one of IDEA’s broader categories. Furthermore, for a child to be eligible for services, one must be able to document that the child’s diagnosable disability has an educational impact *and* that the disability warrants special education services. Therefore, not all children who may meet *DSM-IV-TR* diagnostic criteria would qualify for services under IDEA. For example, a child with a hearing loss may not qualify for services if it is demonstrated that he or she is making academic progress at a rate commensurate with that of his or her peers. Furthermore, several criteria for determining eligibility include provisions stating that the child’s learning problems cannot be due to environmental, cultural, or economic disadvantage. Practitioners should be aware that states receiving IDEA funds must serve students with these recognized disabilities, but many states have adopted classification systems that may expand upon these definitions. IDEA does not require education agencies to label students in order to receive services. Indeed, some states have adopted noncategorical service delivery systems.

Several IDEA disability classifications have fueled long-standing debates. In the most recent revision, the criteria for determining whether a child has a specific learning disability was modified, changing the controversial requirement that a child display a severe discrepancy between intellectual ability and academic achievement to permitting the use of a process based on the child’s response to research-based intervention. Under this response-to-intervention approach, children who demonstrate persistent academic difficulties despite the implementation of empirically supported interventions may be considered eligible for special education services. States may choose to continue to use the discrepancy model between the child’s intellectual ability—typically as measured by a norm-referenced standardized assessment—and the child’s achievement in one of several areas. These include oral expression, listening comprehension, written expression, basic reading skill, reading comprehension, mathematics calculation, and math reasoning. Regardless of the method used, an observation of the

child's academic performance by an observer other than the teacher within the classroom is mandated. Furthermore, in determining eligibility, teams must rule out sensory impairments; mental retardation; emotional disturbance; and environmental, cultural, and economic disadvantage as possible causes of the child's learning challenges.

The federal definition of *mental retardation* has also been scrutinized. To be classified as qualifying for services as a student with mental retardation, a child must show significantly below average performance—generally defined as below two standard deviations below the population mean—on a measure of general intellectual functioning. This is often demonstrated through use of standardized intelligence tests. However, IDEA does not explicitly mandate using intelligence tests. States may choose to use other procedures that are deemed valid and nondiscriminatory. In addition, the child must demonstrate significant deficits in academic functioning and adaptive behavior delays. Adaptive behavior refers to the child's ability to meet age-appropriate expectations for independent personal and social functioning. Critics of this definition have cited the overrepresentation of minority students in special education as indicative of unfair assessment techniques and procedures for identifying students with mental retardation.

*Emotional disturbance* is another IDEA definition that has caused significant controversy. The term includes students demonstrating difficulty learning that cannot be explained by cognitive, sensory, or health factors; difficulty building and sustaining satisfactory interpersonal relationships with peers and adults; inappropriate types of behavior or feelings under typical circumstances; a pervasive mood of unhappiness or depression; or a tendency to develop physical symptoms or fears related to personal or school problems. These problems must occur over a long period of time to a marked degree and must adversely affect the child's academic performance. The federal legislature's decision to exclude children who are socially maladjusted from this category, unless they also meet criteria for emotional disturbance, has sparked the most controversy. Several practitioners believe that the two cannot be treated as distinct problems. Noting differences between the IDEA and *DSM-IV-TR* systems of classifying disorders, practitioners should not assume that a child meeting *DSM-IV-TR*

criteria for an emotional disorder would automatically qualify for services under IDEA.

## Procedural Issues

Practitioners working within school systems should be familiar with several procedural elements incorporated into IDEA. The law outlines detailed procedures for conducting evaluations for determining eligibility. Specifically, IDEA Part B mandates that eligibility decisions are made using a variety of technically sound assessment tools and strategies (e.g., standardized assessment data, information from the parents, curriculum-based assessment measures) and that multiple sources of data must inform eligibility decisions. Assessment tools must also be considered fair for use with the particular child and valid for their intended use. After completing these assessments, a team—whose members are defined by IDEA regulations—must meet to determine whether the child meets eligibility criteria as a child with a disability and whether the child needs special education services.

Once a child has been found eligible for special education services, a team must convene within 30 calendar days to develop an Individualized Education Program (IEP). The IEP is a document that records the child's individualized education plan, including information regarding the child's disability and its impact on participation in the general curriculum, a description of special education services and supports the child will receive—including the extent to which the child will not participate with nondisabled peers in a general education classroom, a plan for monitoring the child's progress toward annual goals, and a plan for transition services.

In making placement decisions, teams must select the "least restrictive environment" in which the child can receive the services needed in a setting as close as possible to an age-appropriate general education classroom. The intention behind this terminology was to ensure that to the greatest extent possible, children with disabilities are educated with their nondisabled peers. School teams should carefully weigh whether the child can be educated within the regular classroom with special education supports, or whether the benefits of a special education classroom would outweigh the benefits of placement with support in the general classroom, including consideration of whether a child's behavior within a general education classroom is too disruptive or dangerous to others. The challenge

to school teams when making placement decisions is to balance a child's right to an education in the least restrictive environment with the right to an appropriate education. Unfortunately, the lack of research-based evidence to support placement decisions can make this decision challenging.

IDEA also contains several safeguards designed to protect the rights of parents and their children with disabilities. Specifically, IDEA outlines procedures to ensure schools obtain written consent from parents before initiating evaluation, eligibility determination, and placement in special education. The law also documents procedures for providing parents with notice of these events, specifically stating that this notice must be provided in the parents' preferred mode of communication. Schools must also provide parents with documentation of their rights and of the protections available to them and their children. Practitioners should familiarize themselves with these statutes and state/district interpretations of these guidelines.

## Part C

IDEA's Part C was developed in recognition of the importance of early identification and intervention for very young children with disabilities. Part C encourages states to develop statewide coordinated multidisciplinary programs to serve the needs of infants and toddlers with disabilities and their families. Each state receiving Part C funding must identify a lead agency (e.g., department of health, education, social welfare) to coordinate and monitor services and an interagency coordinating council to ensure coordination among various agencies providing services. Furthermore, these states must also establish a public awareness program and a child-find system to promote early identification of young children with disabilities.

Children eligible for services under Part C are children under age 3 who are experiencing significant developmental delays in cognition; in fine or gross motor skills; or in communication, social/emotional, or adaptive development or who have been diagnosed with a physical or mental condition that has a high probability of resulting in developmental delay. States may also choose to serve children defined as at risk for developing a significant delay either due to biological or environmental factors.

Procedures for evaluating and determining eligibility for Part C services are fairly similar to those for Part B. However, the legislation was written to ensure

family participation throughout the process. Therefore, the eligibility determination process must include gathering information regarding the family's concerns, priorities, and resources, and identification of services necessary to help the family meet the developmental needs of their child. If a child is found eligible for services, the team—including the parents, a service coordinator, a person directly involved in conducting the evaluations, and persons who will be providing services—convenes to create an individualized family service plan (IFSP) rather than an IEP. The IFSP is similar to an IEP but emphasizes the role of the family. Therefore, the IFSP must contain a statement of the family's resources, priorities, and concerns and may include direct (focused on the child) as well as indirect (focused on the family) interventions in recognition that addressing the family's needs may be necessary to support the child.

Unlike services for school-age children, to the greatest extent possible, services under Part C must be delivered in the child's natural environment. In order to facilitate smooth delivery of services, a service coordinator representing the profession most immediately relevant to the child's or family's needs, and who will be responsible for implementing the plan and coordinating with others, is also identified on the IFSP. The IFSP must also document steps that will be taken to transition a child with a disability to preschool or other services. Unlike an IEP, this plan is reviewed at least every 6 months. Similar to Part B, Part C also outlines specific procedural rights for parents.

## Professional Issues

In aligning more closely with No Child Left Behind and its emphasis on highly qualified professionals and documentation of outcomes, the revised IDEA may be expected to impact service providers in several ways. Although not explicitly stated in IDEA in relation to counselors, language emphasizing "highly qualified" professionals resonates throughout the legislature. As a result, several school systems receiving IDEA funds are requiring counselors and psychologists to demonstrate appropriate credentialing. The revised IDEA is also more outcome-oriented than previous versions, focusing on assessing the progress of students with disabilities. As a result, counselors and psychologists practicing within the schools may be expected to write objective, attainable goals, provide methodology for assessing progress toward these goals, and document

progress. Related to this emphasis on adequate progress, IDEA stresses the use of evidence-based interventions, encouraging counselors to select interventions with a strong empirical foundation when providing services within the schools.

## INDUSTRIAL/ORGANIZATIONAL PSYCHOLOGY

---

Industrial/organizational psychology (I/O psychology) is a branch of psychology that explores the principles of psychology in relation to the workplace. Psychology principles applicable to the work setting are those mentioned in learning theory and aspects of social psychology as well as motivational and emotional principles. All of these principles can be used by counseling professionals to develop training and incentive programs, to form work groups and solve interpersonal problems, and to motivate and satisfy employees. Like counseling psychology, I/O psychology is based on the scientist–practitioner model. This model guides I/O psychologists in two ways: (a) conducting research and understanding the scientific principles in working with organizations, which is the scientific portion, and (b) providing the basis for high quality and effectiveness for the organization, which

is the practitioner component. This entry discusses the history of I/O psychology, the services I/O psychologists perform, and the relationship between I/O psychology and counseling.

### History and Major Contributions

It is not known exactly when I/O psychology began; however, in 1897, W. L. Bryan discussed how telegraphers learn the skill of sending and receiving Morse code messages. Six years later, Walter Dill Scott wrote *A Theory of Advertising* in which he applied psychology to business. Lillian Mollen Gilbreth announced in 1908 that human beings are the most important factors in industry and that they were not being acknowledged in the manner that they should. In 1911, engineer Frederick W. Taylor became conscious of how redesigning the workplace can achieve both higher efficiency within a company and higher compensation for employees. These people were the pioneers of the industry and contributed immensely to the world of I/O psychology and to how it is used today.

Although these individuals set the tone for the field, the onset of World War I had the first great impact on I/O psychology. Developed by then–American Psychological Association (APA) president Robert Yerkes and others, Army Alpha and Army Beta tests were used to determine the general intelligence of recruits so they could be placed in the appropriate positions, signifying the role of psychologists in work placement. The Alpha test was used for recruits who could read, and the nonverbal Beta test was used for those who could not read at all or who could not read English. These tests were used in placing recruits into appropriate positions.

As the war ended, it seemed that the use of I/O psychology was ending too. However, in 1920 the Hawthorne studies propelled I/O psychology by suggesting that employees' productivity improved because of the attention they were receiving from managers and employers, not the effects of the workplace lighting as the original research question suggested. This idea, referred to as the Hawthorne effect, had a significant impact in the history of I/O psychology, as it encouraged psychologists to focus more on human relations in the workplace and boosted the importance of this area of psychology.

As psychologists in the field polished their techniques on employee selection and placement, the Army again requested that psychologists develop a

test that would divide recruits into groups based on their ability to learn the duties and responsibilities needed to be a soldier. Psychologists met this request by developing the Army General Classification Test (AGCT); other methods for selecting recruits for officer training, proficiency tests, and aptitude tests were also developed. As World War II continued, I/O psychologists also used their skills to keep the nation's workforce productive to support the war need. Industries were finally realizing that techniques and principles learned from social psychology were applicable in business in areas such as selection, training, and machine design.

As the United States evolved during the 1950s and 1960s, the civil rights movement made its impact on the field of psychology in general and specifically on I/O psychology. With the passage of the Civil Rights Act, business and industry came under scrutiny because they employed disproportionately few minority psychologists; however, because the law enforced the issue of discrimination in employment, the need for I/O psychologists increased. I/O psychology advanced greatly during the 1980s and 1990s, as more sophisticated research tools assisted psychologists in generating more information about psychology and the work world and in developing new tools such as the Armed Services Vocational Aptitude Battery to assist in personnel selection and classification.

Another important factor in the development of I/O psychology is the changing demographics in the workforce. The number of employed women, Latino/as, and Asian Americans continues to increase, and more individuals, such as customers, workers, and vendors, have English as their second language. In addition, minorities such as women are entering higher-level managerial positions. I/O psychologists are needed to help promote diversity in the work environment and to educate employees about navigating diverse environments and resolving conflict that may arise among different groups. With movements toward flexible, family-friendly work schedules and policies, I/O psychology has come to be a cornerstone in keeping an organization running smoothly and efficiently.

### What I/O Psychologists Do

I/O psychology is relatable to human resource management (HRM) in selecting employees and managing the work environment. Although there are similarities in that both are involved in employee

selection, I/O psychology focuses more on the use of psychological principles, psychological tests, behavioral interviews, work samples, bio-data, and assessment centers rather than the use of unstructured interviews and reference checks that HRM professionals employ. Further, I/O psychology places more emphasis on the people of an organization (e.g., motivating and retaining, enhancing productivity) instead of the technicalities of actually running the organization (e.g., policy and procedure enforcement, worker benefits). Finally, a misconception of I/O psychologists is that they provide psychotherapy for employees. Although there are psychologists who do provide in-house psychotherapy to employees with a range of problems, such as those who work in Employee Assistance Programs (EAPs), I/O psychologists do not; instead, they often employ research and interventions with specific organizations to increase effectiveness of that organization.

I/O psychologists provide several different services for those with whom they work, including selection and placement of employees, training and development, developing and evaluating performance appraisal systems, organizational development, enhancing quality of work life, and evaluating ergonomics to name a few. I/O psychologists who provide selection and placement services focus on methods for selection, placement, and promotion of employees by choosing and developing tests aimed at assisting clients in accomplishing these tasks. For example, a psychologist may use testing information to help a company choose who to hire for a manager position. In providing training and development services, I/O psychologists determine what skills and methods are needed to improve employees' job performance. For example, a psychologist may work with a company to implement a leadership development program for managers and potential managers. Those who provide performance appraisal services create ways to determine how well employees are actually performing their job. Last, I/O psychologists who provide services in relation to ergonomics are concerned with the equipment and machinery related to human skills as well as with how the organization is designed. These psychologists usually work with engineers and others in the technical profession to help make the workplace safer and enable employees to be more resourceful.

In addition to these areas, there are several services I/O psychologists provide that relate to the field of counseling psychology. These include (a) enhancing

employee motivation; (b) improving organizational communication; (c) addressing group behavior, team management, and conflict, (d) addressing employee satisfaction, and (e) executive coaching. These services are discussed in more detail below.

### **Motivation**

In addressing motivation, I/O psychologists call on psychological theories such as consistency theory and Maslow's hierarchy of needs to examine individual predispositions related to motivation. Factors that contribute to a motivated predisposition include self-esteem, intrinsic motivation tendency, and a need for power and achievement. More specifically, employees who have a high self-evaluation will work harder so that their behavioral outcomes match their expectations. Although individuals with high self-esteem may be likely to perform better than those with low self-esteem, this may be true only in cultures where superior job performance is socially valued. Individuals who are intrinsically motivated are those who receive satisfaction in accomplishing a goal or task in and of itself and not just in the rewards gained from doing so.

An individual's predisposition for motivation may also be affected by her or his need for achievement and power. For example, Michael Stahl found that individuals who scored high on both need for achievement and power on the Job Choice Exercise could be classified as having a high level of managerial motivation. Thus, individuals with a high need for power and achievement are more likely than those with a low need for power and achievement to be motivated to work for promotions that place them in a position of control and influence. Other factors that contribute to employee motivation include whether or not an individual's needs are being met, achievability of goals, and the incentives received for meeting work goals.

In addressing motivation, I/O psychologists may conduct assessment related to predisposing factors of motivation as mentioned above and assess employees' goals or help employees develop achievable goals. Further, I/O psychologists may work with organizations to develop and assess evaluation and feedback systems and reward systems.

### **Organizational Communication**

An important aspect of any group of individuals is communication. Within an organization, effective communication can increase employee satisfaction

and commitment and can actually help increase the effectiveness of the organization itself. Within an organization, smaller social and functional groups exist in which communication occurs both within and between groups. Types of groups that exist include work teams, levels of management, committees, and social groups. Communication varies in the ways it is both sent and received depending on which groups or individuals are communicating.

Michael Aamodt defined four types of organizational communication: upward, downward, business, and informal communication. Upward communication is that which goes from subordinates to superiors, while downward communication goes from superiors to subordinates. Business information is the relay of information that is business-related and can occur among customers as well as managers and employees. The fourth type is informal communication and consists of unofficial information that is transmitted through groups of workers or the organization itself.

Just as communication occurs within and between groups, another important component is interpersonal communication. Interpersonal communication occurs from one person to another and includes actual spoken words as well as nonverbal cues such as body language and use of space. It is also important to note that much of interpersonal communication is greatly influenced by one's culture. While some cultures value an expressive style of communicating, others pay more attention to the factuality of what is stated.

I/O psychologists address communication issues by assessing the current forms of organization communication through surveys, interviews, and reviews of materials such as manuals and memos. Further, I/O psychologists will work with organizations to improve communication, providing feedback on current communication systems and recommendations for improvement such as incorporating different forms of communication systems. In addition, I/O psychologists may provide training relating to communication skills, such as telephone and e-mail etiquette, interpersonal communication, and verbal and nonverbal communication.

### **Group Behavior, Teams, and Group Conflict**

In order for individuals to be considered a group, they must meet the following four criteria: Members must see themselves as a unit, rewards must be provided to members, something that affects one member in turn affects the entire group, and members

of the group must share a common goal. One of the factors that may affect group performance is group cohesion. An important component of group cohesion is having a shared set of attitudes and beliefs. Typically, members in a group perceive themselves as being more similar to other group members than to individuals not included in the group.

Similar to groups is the concept of teams. Teams are groups of three or more individuals who work together to achieve a specific work-related task or goal. Work teams are distinguished from one another by their specific objectives. Susan Cohen and Diane Bailey defined four different types of teams. *Work teams* are fairly stable teams that have the objective of producing goods or providing a service. Within work teams, there are no supervisors; rather, each member plays an equal role in contributing to the goal of increasing product or service quality. *Parallel teams* are representative of different departments or units and are indeed parallel to the organization as a whole. The objective of parallel teams is to work as a problem-solving unit and to provide feedback or recommendations to superiors within the organization. The next type of team is *project teams*. These teams are formed for a limited time basis with the objective of completing one task or goal for the organization. *Management teams* are responsible for overseeing the work of units below them. For example, a group of managers of an organizational department may be responsible for supervising employees within that department to ensure optimal performance of the department.

Just as conflict occurs among individuals, it also occurs within and between groups. Conflict is a reaction that occurs when someone interferes with an individual's need to achieve a goal or accomplish a task, when rights have been violated, or when expectancies of a relationship are broken. Conflict can be either functional or dysfunctional. Dysfunctional conflict is harmful to the working environment and prevents goals from being achieved, while functional conflict can increase competition as well as prevent larger conflicts later on. Because conflict is unavoidable, the most important aspect of conflict is how it is dealt with. Members of a group should determine early on what attitudes toward conflict will be and how conflict should be handled.

In working with groups and teams, the I/O psychologist will assess the current functioning of the group in relation to its structure and function (e.g., leaders and followers; how work is accomplished), cohesion, communication, and conflict. The I/O psychologists may

provide services such as communication skills training, feedback, and recommendations to enhance group functioning, activities to build group or team cohesion, and instruction and facilitation of conflict resolution.

### ***Employee Satisfaction and Commitment***

Organizational commitment and employee satisfaction are important aspects of an organization that affect employee behavior. Organizational commitment is the amount of allegiance felt by an individual toward an organization and can be broken down into three components: affective, continuance, and normative commitment. *Affective commitment* deals with the emotional ties to an organization and the extent that an individual cares about the organization. *Continuance commitment* is an employee's decision to stay with an organization due to time and effort already expended for the company. *Normative commitment* is commitment based on feelings of obligation toward an organization. The levels of each type of commitment may vary among individuals, and different combinations of strengths and types (affective, continuance, and normative) of commitment will result in differing employee behaviors.

Along with organizational commitment, job satisfaction plays a major role in employee attitudes and behaviors. Job satisfaction is influenced both by individual characteristics and the actual organization as well as by whether or not an individual is a good fit for an organization. Timothy Judge, Edwin Locke, and C. C. Durham proposed four personality characteristics that may contribute to a higher level of job satisfaction: emotional stability, self-efficacy, self-esteem, and an external locus of control. In order for an individual to be an appropriate fit with an organization, it is important that the values, skills, interests, personality, and lifestyle of the individual are similar to those of the organization. Because a great deal of satisfaction and commitment is related to personal characteristics, counseling psychologists can play an important role in helping assess an individual's wants and needs and in determining how they can contribute to job satisfaction.

### ***Executive Coaching and Consultation***

Executive coaching has been in existence since the 1940s but has only recently received a great deal of attention in research on the effectiveness of this practice. Richard Kilburg defines executive coaching as a relationship between a client and an executive coach

(or consultant) who assists the client in identifying organizational goals and implementing interventions to achieve those goals based on a formal agreement. Executive consultants provide an outside perspective to organizational executives by helping organizational leaders during times of organizational transition, with problem employees, and with team and interpersonal conflicts and by improving performance levels.

It is important to distinguish executive coaching and consultation practices from the practices of counseling and psychotherapy. Although there are many similarities between counseling and consultation, consultation and executive coaching have an overarching goal to improve an organization or workplace rather than a single individual. Executive coaching covers a broad array of workplace issues and can last anywhere from a few minutes to several hours. Also, while counseling is dyadic in nature and focuses on personal issues, consultation is triadic and focused on work-related issues.

## Counseling and I/O Psychology

Similar to I/O psychology, counseling psychology's historical roots are tied to the military and the world of work, helping individuals to make the most out of their potential and to develop throughout their work careers. As a specialty of psychology, counseling involves a philosophy and working approach that resemble those of many areas of I/O psychology. For example, Sandra Shullman identified many overlaps between counseling psychology and consultation, a service often provided by I/O and counseling psychologists, such as recognizing and building on strengths, assisting individuals to achieve optimal functioning, identifying and addressing the impact of systems, and empowering consultees or clients to foster change. Counseling psychologists, trained as professional psychologists, develop competency in (a) gathering information and making conclusions or diagnoses; (b) consulting at the individual, group, and system levels to solve problems; (c) providing interventions to address problems; and (d) developing new knowledge through designing, implementing, and evaluating research. These foundational and functional competencies of professional psychology provide the groundwork on which counseling psychologists can offer services, as counseling psychology continues to expand to areas outside of traditional practice arenas and allows counseling psychologists to provide

consultation services in areas such as health care, equal employment opportunity, safety, workers compensation, employee assistance programs, labor relations, employee outplacement, and recruitment. Clyde Crego notes that this overlap and generalization of competencies suggests that it is highly likely that counseling psychologists and students in training to become counseling psychologists can, with appropriate training, adapt their skills in order to provide I/O related services in a variety of settings.

## INTERNALIZING PROBLEMS OF CHILDHOOD

---

Internalizing problems of childhood are broadly defined as problems that occur within the child. Children with internalized problems often appear

withdrawn, fearful, and shy. Internalized problems are managed within the child rather than being acted out externally in the environment. Beyond differing in their diagnostic criteria, externalizing problems differ from internalizing problems primarily in their expression. However, there is significant evidence that externalizing problems and internalizing problems occur comorbidly. Broadly speaking, the class of internalizing problems in childhood includes depression and anxiety. Subcategories of childhood anxiety disorders are also internalized disorders and include separation anxiety disorder, panic disorder, social phobia, simple phobia, obsessive-compulsive disorder, posttraumatic stress disorder, and generalized anxiety disorder. Similarly, subcategories of depressive disorders have been identified and include major depressive disorder, dysthymia, cyclothymia, and bipolar disorder.

### Internalizing Problems Defined

Though the next section is not comprehensive, its intent is to provide an overview of some internalizing problems in childhood, guided by the diagnostic criteria of the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)*. Only the broad categories of depressive disorders and anxiety disorders will be reviewed.

### Childhood Depressive Disorders

As one of the most pervasive disorders, depressive disorder (often referred to as mood disorder) has a tremendous impact on a child's energy, mood, and expression of emotions. Children who suffer from any form of depression experience challenges with peer relationships, familial relationship, academic success, and overall psychosocial development. Though many similarities exist between depression in adults and depression in children, there are some distinct differences. Specifically, children exhibit an irritable mood and, at times, an inability to sit still, including fidgeting or pacing.

Depression has a profound impact on a child's well-being similar to its effect on adults. Children with depression experience profound sadness, frequent periods of crying, feelings of helplessness and/or hopelessness, and a decrease or increase in appetite. Along with these symptoms often come feelings of discouragement or worthlessness and a loss of interest in pleasure and subsequent disinterest in

previously interesting activities. Children with depression may be fearful and anxious and often experience a significant drop in school performance. Finally, these children may experience significant changes in their sleeping habits, specifically an increase or decrease, and they often complain of physical aches and pains that have no medical explanation.

### **Childhood Anxiety Disorders**

Children experiencing significant anxiety often experience intense fear, irritability, worry, and overall uneasiness. Anxiety can have a profound impact on a child's well-being and can influence or profoundly affect the child's school success, relationships with peers, self-esteem, and ongoing anxiety into adulthood. The specific symptoms of anxiety disorders differ according to diagnosis; therefore, below is a general overview of the broad diagnostic category of childhood anxiety.

When children experience a general sense of anxiety, they worry about things that occur in their everyday lives, such as school activities, peer relationships, and extracurricular activities. These fears often result in lower self-esteem, physical complaints without a medical explanation, and a strong need for reassurance. Other anxiety problems may be a result of unrealistic fear of a particular situation or object (phobias). Examples of such phobias may include fear of storms, snakes, spiders, height, water, or social situations. Children with phobias may attempt to avoid situations that may expose them to the environment or object that produces their fears, thus restricting their activity and social interaction. Other types of anxiety may manifest in a child through an intense fear of leaving his or her parents (separation anxiety), through patterns of repetitive thoughts or behaviors (obsessive-compulsive disorder), or a constant replaying of a stressful event (posttraumatic stress). Anxiety overall limits children's willingness and at times capacity to freely experience the world and subsequently impacts their overall psychosocial development.

There is a high degree of comorbidity between anxiety and depression in children, meaning that children with symptoms of one, either anxiety or depression, often eventually exhibit symptoms of the other. It is important to note that to be considered significant, all symptoms associated with any of these internalizing problems must be present beyond what is to be expected with normal development and to a significant degree must cause problems with

psychosocial and educational development. Any single symptom cannot lead to a diagnosis of one of the above internalizing disorders.

## **INTERNATIONAL DEVELOPMENTS, COUNSELING**

---

Historically, interest in international psychology dates back to professional affiliations created in Paris over a century ago at the First International Congress of Psychology. Since then, a variety of organizations continue to support the professional interests of psychology worldwide (e.g., the American Psychological Association's [APA's] Division 17—International Special Interests Group, and Division 52—International Psychology). From a discipline-specific standpoint, the field of counseling psychology brings several significant strengths to the field of international psychology, including its traditional emphases on mental health, vocational assessment,

and prevention, to name but a few. These strengths, in combination with its longstanding commitment to multiculturalism and diversity, suggest that counseling psychology may be uniquely suited to meet challenges facing the field of international psychology today.

## **Current Growth Within the Field**

### ***Globalization***

Current growth within the field has, by and large, been fostered by the rapid and expansive impact of economic and technological globalization. This expansion is of particular interest at present, as the impact of globalization transforms both personal and professional roles in a variety of cultural arenas. The potential benefits of increasing the international scope of counseling psychology are myriad and include creating a worldwide forum for examining whether accepted traditional psychological paradigms and practices are generalizable to other cultures. Globalization also allows for an expansion of our current understanding of human strengths and resiliency as they relate to cultural context and provides a much-needed opportunity for incorporating diverse international multicultural perspectives within the profession.

### ***Opportunities and Risks***

While an expansion of international psychology offers many new opportunities for cross-cultural collaboration, it also presents several risks. Chief among these is the need to guard against the wholesale exportation of professional ideologies as they relate to practice, education, and research. As training programs, research methodologies, and journal publications based in the United States still account for the greatest proportion of counseling activities worldwide, several significant concerns are worth noting. Many methodologies, theories, and practices derived from current systems may, at best, ignore important and significant cross-cultural differences when transplanted to new cultures, and at worst, they may extend ethnocentric biases regarding human behavior to local psychologies. Examples of this include an over-reliance on diagnostic systems based on traditional medical models and the exportation of commonly used psychological tests to evaluate behavior. The generalization of Western diagnostic systems to other cultures may be inappropriate in many instances and may not reflect cultural norms for

both functional and symptomatic behaviors. The use of psychological tests with individuals for whom their use has not been validated through the construction of appropriate norm groups, or that have been translated without evaluating their appropriate equivalency, may lead to misdiagnosis or an assignment of problems where none exist. A wholesale exportation of current models and methodologies also limits opportunities to expand our knowledge base in valuable ways that have the potential to validate (or invalidate) important concepts and practices through cross-cultural collaboration. Opening the field to alternative methodologies may increase understanding of how biases inherent in traditional systems operate when applied both to one's own and to other cultures.

The expansion of international counseling, by its very nature, has produced a unique set of circumstances that challenge traditional notions of psychological health as they relate to counseling practices. The by-products of globalization, which include socioeconomic conditions such as immigration, economic displacement, and international conflicts, have created a new generation of individuals with human problems for which traditional treatment methodologies may be of limited use. These conditions require the competent professional to be creative in new and innovative ways that may be inconsistent with traditional notions of training and educational practices. Modern conceptualizations of identity and psychological health are changing rapidly as classical notions of identity are displaced along with individuals and cultural traditions. Our understanding of the particular determinants of behavior is very much influenced by whether or not a particular culture embraces an individualist versus collectivist view of identity. While an individualist focus can be essential for understanding certain behaviors, it often ignores context and underestimates the complexity of the many sociocultural determinants of behavior. Nor can the impact of social policies on the global community or issues of social justice be ignored, as they profoundly influence how we choose to localize the causes and, ultimately, the treatment of psychological problems.

## **Critical Issues in Professional Development**

### ***Professional Collaboration***

The creation of a truly international form of counseling psychology will require professional

collaboration at many levels to identify and prioritize aims and objectives. Currently, counseling psychology exists as a specialty, by name, in only a handful of countries, although the common practices of counseling psychology, while not formally identified as such, may be subsumed under other disciplines. Thus, efforts at professional collaboration may be easily frustrated by an inability to identify international colleagues or contexts in which to develop projects of mutual interest. Fortunately, a variety of professional organizations (e.g., the International Congress of Applied Psychology and APA's divisions 52 and 17) and programs (e.g., the Fulbright Scholar program) already exist to promote mutual international interests and development via conferences, exchange programs, and professional research and journal collaboration both here and abroad. Other organizations have also worked to promote specific venues (e.g., journal issues devoted to international articles) that examine the psychological practices and perspectives of other cultures and address issues unique to international counseling psychology.

### ***Ethical Practice***

Another critical issue for the international expansion of the profession is defining what constitutes appropriate and ethical modes of practice and how best to determine culturally appropriate standards for a variety of professional helping behaviors (e.g., the appropriateness of meeting clients in their homes or cultural values related to personal space or physical touching). Many contemporary problems and adjustment issues may be ill suited to traditional treatment delivery methods (e.g., talking therapies) and will require innovative treatment strategies and flexible professionals who can develop new methodologies and modes of delivery. Attention must also be given to training and recruitment issues, both at home and abroad, to ensure that the concept of international multiculturalism extends to those who professionals train and to how they train them.

### **Social Policy and Special Interests**

Many proponents of international psychology argue that the psychopathology of the new world order often rests in extreme social conditions, and special attention should be directed to issues of social justice as they relate to the delivery of mental health services. Global conditions have a differential impact on the

psychological well-being of vulnerable groups such as women, children, displaced persons, and other marginalized minorities. New types of special populations have also been created by changes in national, economic, and technological boundaries. Populations uprooted by international conflicts and rapid economic changes require innovative strategies that offer support for victims of trauma and interpersonal violence and that provide new venues for reworking intervention efforts related to basic survival issues as well as to psychological health. Acknowledgment of the unique psychosocial forces that impact the mental health of women and children seems especially critical and includes recognition of issues such as interpersonal violence, poverty, employment conditions, child and family care responsibilities, health care, and access to educational opportunities.

### **The Necessity of Growth**

The global forces currently acting at breakneck speeds suggest that implementing a strategic plan for international counseling is not only desirable but absolutely necessary. Globalization has the potential to provoke an identity crisis of sorts not only for the profession but also for how psychological health is viewed worldwide. As traditional values are subsumed by larger world changes, there exists the potential for an absence of consensual validation for standards of "normal" behavior. Counseling psychology has been at the forefront of supporting multiculturalism through its commitment to diversity issues, and an expansion of international counseling efforts is a natural extension of this commitment. As the traditional distinctions between psychological disciplines diminish on a practical level, the question then becomes, how might the technological innovations that have created unprecedented access to a global psychological community have the potential to empower the traditional mission of counseling psychology in significant ways? A failure to move forward in a thoughtful and directed manner at this critical juncture not only incurs the risk of professional stagnation but threatens the growth and the integrity of the discipline as well as its ability to fulfill its mission in a meaningful way. A shift toward a universal multicultural international model that advances the discipline must be based on a flexible worldview that incorporates ethnic diversity as well as diverse multicultural perspectives that can validate

and expand our understanding of human growth and potential and provide us with a new way of looking at problems in “normal living.”

## INTERNATIONAL DEVELOPMENTS, COUNSELING PSYCHOLOGY

---

Clearly, the world is rapidly changing and becoming a global village with increased interdependence, communication, travel, migration, and trade between countries. This entry summarizes the international

developments in counseling psychology in the United States and worldwide.

### In the United States

The U.S. counseling profession has a long and distinguished history, evolving from the vocational guidance movement in the late 19th century to a strong counseling psychology specialty within the discipline of psychology in the 21st century. The specialty educates individuals through accredited training programs, generates knowledge from research, credentials members to function as professionals, and is regulated through organizations established for more than 50 years.

The profession made several early attempts to become internationalized. For example, after World War II, U.S. counseling psychologists consulted with Japanese education faculty about establishing counseling services. More systematic efforts to increase cross-cultural communication within the profession began in the mid-1960s with the creation of the *International Journal for the Advancement of Counseling*. In the 1980s, a few counseling psychologists were granted Fulbright professorships. In 1988, Bruce Fretz, then the incoming editor of *The Counseling Psychologist (TCP)*, began a new section within this journal called The International Forum, publishing articles primarily by U.S. scholars about their experiences working abroad. In 1989, the Minnesota International Counseling Institute (MICI) was created by counseling psychology faculty at the University of Minnesota, namely Thomas Skovholt, Sunny Hansen, John Romano, and Kay Thomas. The MICI is a biennial gathering of international practitioners and scholars to advance the science and practice of cross-cultural counseling. In 1991, Paul Pedersen published a landmark article proposing that culture, defined broadly, is generic to all counseling. In essence, Pedersen broadened the conceptualization of culture to expand the growing multicultural movement to include cross-cultural counseling. For the next 15 years, Pedersen provided leadership in promoting the internationalization of the profession. However, by the mid-1990s, the internationalization of the profession was not widely accepted or even well understood.

In 1997, the incoming editor of *TCP*, P. Paul Heppner, renewed the focus on international issues by (a) assigning scholars who were leaders in the international movement in counseling psychology as series coeditors (Frederick Leong and Paul Pedersen, and later Joe Ponterotto and Dave Blustein) of the

International Forum, (b) changing the review process to be more culturally sensitive for international authors submitting manuscripts, and (c) appointing the first scholar from outside the United States (S. A. Leung from Hong Kong) to serve as associate editor. Because of the work of the series coeditors, more international colleagues were encouraged to submit manuscripts, the review process was more effective, and more international scholars began to publish in *TCP* and in other counseling journals, resulting in a slow increase in communication around an international perspective in counseling psychology.

More important, between 1997 and 2003, a number of articles and books appeared by Pedersen, Leong, and other colleagues more fully articulating a strong rationale for internationalizing counseling psychology in the United States and emphasizing the pervasive role of culture in all dimensions of counseling. These publications increased awareness that culture affects behavior and thus is a very important context in which to understand the counseling process. In 2003, Louise Douce, as president of the American Psychological Association's (APA's) Division 17 (Counseling Psychology), created a forum at the annual APA convention for counseling scholars interested in international issues to discuss common goals. Two years later, Heppner, as then president of Division 17, expanded the international scholar's breakfast and reception at the APA convention to welcome international guests, promote collaborative relationships across different countries, and give scholars an opportunity to learn from each other. He also initiated, in conjunction with Lawrence H. Gerstein, an international section within Division 17.

In 2006, there was a growing awareness of the utility of cross-cultural issues in counseling, and growing numbers of international graduates were joining the ranks of counseling professionals. The infrastructure of the international counseling movement also expanded as did the availability of outlets for publication. Consequently, communication among counseling leaders worldwide has increased, and the focus on international issues within counseling psychology in the United States has accelerated.

### Around the Globe

The counseling profession is active worldwide. However, there are many differences in the identity of counseling psychologists, the credentials required to

function as such professionals, and the presence and infrastructure of associations representing this occupational group.

The profession is blossoming more in Asia than in other regions of the world. In general, counselors and counseling psychologists can be found in Taiwan, China, Japan, South Korea, Thailand, Malaysia, Hong Kong, Singapore, the Philippines, and to some extent, India and Pakistan. In only a few Asian countries is it possible for counselors (e.g., Japan) and counseling psychologists (e.g., Taiwan) to be licensed. There are, however, many organizations representing such professionals.

The counseling profession also can be found in the Southern Hemisphere. Counselors and/or counseling psychologists are available in Australia, New Zealand, and Fiji, along with several organizations.

Counseling is not as popular in the Middle East, Eurasia, southeastern Europe, and western and central Asia. Although counselors can be found in countries such as Israel, Lebanon, Saudi Arabia, Egypt, Jordan, Kuwait, the United Arab Emirates, the Palestinian territory, Turkey, and Iran, they are a recognized specialty only in Greece and can be licensed in only a few of these countries (e.g., Lebanon, Greece). A wide array of organizations is available along with a division of counseling psychology in the Hellenic Psychology Society in Greece.

The profession is growing in Africa. Counseling psychologists or counselors can be found in Uganda, South Africa, Ghana, Kenya, Nigeria, and Botswana. There are a number of organizations for such professionals. Counselors and counseling psychologists can become licensed only in South Africa.

The counseling profession has a long history in Europe. There are counselors, for instance, in Italy, the Netherlands, Sweden, Great Britain, Ukraine, Slovakia, Portugal, France, and Hungary. In Iceland and Germany, there is no counseling profession, but there are psychologists. Counselors can be licensed in Portugal but not in most other countries mentioned above. Counseling psychologists are licensed in Bulgaria and Ireland. Organizations for counselors exist in many countries. Counselors living in European countries where there is no credentialing may obtain certification from the European Association for Counselling.

Counseling psychology in Canada dates back to the 1950s. Since 1986, the profession has existed as a section of the Canadian Psychological Association (CPA). The CPA accredits doctoral programs in

counseling psychology. Various regulatory bodies recognize counseling psychology as a specialty in psychology. There is no law regulating the title of “counselor” (indicating persons with a master’s degree), but there is certification through the Canadian Counseling Association. Counseling psychologists can obtain a license.

There is little available information on the profession in South, Central, and Latin America. In El Salvador, the differences between counseling psychology and clinical psychology are not stressed. Similarly, counseling is not a separate field in Guyana. In Peru, to become a psychologist, one must complete 6 years of postsecondary education in psychology. Counseling is relatively new to the Bahamas. Only clinical psychologists are licensed.

Finally, a major development in the international recognition of counseling psychology as a specialty was the creation of Division 16 in the International Association of Applied Psychology (IAAP) in 2006. Frederick Leong was instrumental in the development of this new division. The IAAP is the oldest international organization of applied psychology. The 2006 international congress marked the first time counseling psychology had a formal voice in the IAAP.

## Conclusion

Although the inclusion of international perspectives in counseling psychology began in the 1940s, it grew relatively slowly in the U.S. until the beginning of the 21st century. Since 2000, there has been greater interest in international perspectives in counseling psychology in U.S. journals as well as changes in the infrastructure within U.S. professional associations, in the training of students in cross-cultural competencies, and in cross-national communication and collaboration to reach mutually beneficial goals. The profession is vigorously developing worldwide with differing identities, credentialing, training standards and accreditation, and a wide array of service delivery models to address various societal needs for diverse cultures. The profession is active globally and committed to strengthening collaboration among counseling professionals worldwide.

## INTERNATIONAL TEST COMMISSION

---

Test use is an international enterprise. Tests are used widely in education, industry, government—including the military—and in other institutions to assist in decision making. The International Test Commission (ITC)

was established in 1976 to address three test-related issues at an international level: test purchase by unauthorized persons, the questionable quality of some tests, and the unethical use of tests. The ITC's primary mission is to promote an exchange of information on test development and use to improve test-related practices. The ITC works to promote this goal in various ways. First, the ITC maintains a Web site and publishes a quarterly newsletter, *Testing International*, and a scholarly journal, the *International Journal of Testing*. The ITC also promoted the exchange of information through five international conferences to address issues important to test development and use internationally. These include conferences at Oxford University on test use with children and youth; at Georgetown University in Washington, DC, on test adaptation guidelines; in Winchester, England on computer based testing and the Internet; in Williamsburg, Virginia on testing and equity; and in Brussels on psychological and educational test adaptations.

### Developing International Guidelines

Although test use is universal, test development is not. Most countries do not develop standardized tests for internal use; rather, they use tests developed in other countries. These tests typically are translated into the local language and often have unsuitable reliability, validity, and norms for subjects in the countries into which they have been imported. Therefore, under the leadership of Ronald Hambleton, the ITC developed guidelines for test adaptations. The term *test adaptations* refers to a process of altering a test originally designed for use with people who live in one culture (e.g., England) in ways that make the test appropriate for use with those who live in another culture (e.g., Hungary). The ultimate goal is to have the two tests measure the same trait in a fair, equitable, and equivalent fashion.

The ITC has also developed guidelines to encourage best practice in psychological and educational testing. The goal is to provide a common international framework from which specific local standards, codes of practice, qualifications, and user registration criteria can be developed to reflect local needs.

Finally, Internet-delivered computer-based testing is increasing. This development warrants standards for test administration, security of tests and test results, and control of the testing process. Therefore, the ITC has established international guidelines that

highlight good practice issues in computer-based testing and testing delivered over the Internet.

## IVEY, ALLEN E. (1933– )

---

Both of Allen Ivey's parents were born in near poverty during a time when there was no social safety net. Ivey's father's parents had emigrated from Kernow (also known as Cornwall), Great Britain, to the United States and Canada at the turn of the century. Ivey's grandfather died when his father was 9, leaving his grandmother as the sole provider for the family. On his English mother's side, his grandfather lost his inherited local paper due to compulsive gambling. His mother grew up without money for shoes and for required books for school. From his parents' painful childhood experiences, Ivey gained a sense of economic oppression and injustice. Ivey considers himself bicultural, growing up and navigating through his English and Cornish roots, which were not always compatible in their messages with respect to education and achievement.

Ivey grew up in a small house attached to the family store in rural Mt. Vernon, Washington. He

attended a two-room school that was a mile away until he was the only person in the eighth grade. In the school environment, Ivey experienced anti-Semitic prejudice even though he had no knowledge about Jews at the time. He did not share these stories of oppression with his parents. Ivey learned to hate oppression in all forms from his rural childhood. He felt fortunate that his parents' value system of standing up alone for righteousness provided him with a foundation for understanding and supporting multicultural issues.

### Education and Professional Career

Ivey graduated from Stanford University in 1955 and received a Fulbright Scholarship to study social work for a year in Denmark at the University of Copenhagen. His experience in Denmark played a paramount role in developing his contextual approach to counseling. Ivey then attended Harvard University and received his Ed.D. in 1959. During 2 of his 3 years of study at Harvard, he was also working full-time as director of student activities and guidance instructor at Boston University.

At the age of 25, he founded the counseling center at Bucknell University and served as director of counseling. Ivey then assumed the role of director of the counseling center at Colorado State University from 1963 to 1968. In 1966, Ivey received a small grant from the Charles F. Kettering Foundation to identify specific single skills of counseling. This seed would later turn into the articulation of micro skills. Ivey began teaching at the University of Massachusetts, Amherst in 1968, where he served as a professor for more than 30 years. He authored over 35 books and over 200 articles, chapters, and monographs. His work has been translated into 18 languages. In addition to his scholarly work, Ivey founded and is the president of Microtraining Associates, an independent, educational publishing firm. Microtraining Associates has paved the way in producing videos and books related to skills training and multicultural development.

Ivey has been and still is heavily involved and active in the professional community. He served as president of the Division of Counseling Psychology (now Society for Counseling Psychology) of the American Psychological Association (APA). He is a fellow of APA and a diplomate of the American Board of Professional Psychology. In addition, he is a fellow of APA's Society for the Study of Ethnic and Minority

Psychology. Ivey also serves on the Board of Directors of the National Institute for Multicultural Competence. Ivey is a lifetime member of the American Counseling Association and he received their Professional Development award in 1992.

### Contributions

#### *Microcounseling*

Ivey established a structured approach to training therapists in discrete helping skills (micro skills) including attending behavior, open invitation to talk, reflection and summarization, paraphrasing, and interpretation. Instead of focusing only on internal variables, such as self-actualization, therapists can help clients focus on external variables that may disrupt development. The early recognition of the need to explore the cultural environment led to the realization that appropriate attending and micro skills differ from one cultural context to another.

Ivey's motivation and determination for combining his interests in skills training and cultural diversity were inspired by feedback from cross-cultural therapists and his personal values. Other cross-cultural therapists have reported that the same skills did not have the same impact on clients from different cultural backgrounds. Ivey realized that some attending behaviors may damage rapport with clients from another background because of the different cultural meanings of specific attending behaviors. This led to the concept of culture-centered skills. The fundamental key to the development of culture-centered skills is to examine a specific culture, identify concrete skills that may be used with this group, and develop a helping theory that can be tested in application.

Ivey has also infused culture into skills training. His classic text, *Intentional Interviewing and Counseling*, consistently incorporates the theme of developing cultural skills. The sixth edition suggested that the purpose of counseling is to foster client development in a multicultural society. Intentional interviewing requires awareness of racial and ethnic groups that may have patterns of expression and communication different from those of the interviewer.

#### *Developmental Counseling and Therapy*

The study of human development has had a significant impact on Ivey's ideas about culture. Ivey has

drawn from Piaget, Erickson, and Freud to apply developmental concepts directly into counseling in developing developmental counseling and therapy (DCT). In 1986, Ivey suggested that development always occurs within a cultural context, which takes into account both the therapist's and client's cultural and historical backgrounds. Later, in 1991, Ivey elaborated the cultural emphasis in developmental counseling to underline the notion of multicultural development. He proposed that therapists should facilitate clients' movement through different stages of cultural identity development. Ivey believes that therapists help clients move through stages related to conformity, dissonance, resistance and immersion, introspection, and synergistic awareness by focusing on culture in counseling. In this developmental approach, Ivey and his colleagues expanded the definition of culture to include race and ethnicity, gender, religion, economic status, nationality, physical capacity, and sexual orientation. Clients are encouraged to share their stories in ways that promote movement through different types of development. This process may result in both expanded awareness and congruent social action.

### **Multicultural Counseling**

Ivey's prolific work in operationally defining the relationship between multiculturalism and traditional theories of counseling has been influential. Ivey and colleagues concluded that most counseling theories were based on White, middle-class culture, and Ivey questioned the generalizability of these theories to other cultural contexts. Ivey's book was the first theories text to address multicultural issues directly, and it was published before culture became a popular topic in the literature. Since then, the multicultural perspective has been refined in subsequent editions of the text. According to Ivey, D'Andrea, Ivey, and Simek-Morgan, multiculturalism can be described as a meta-theory creating a framework that illustrates how different theories of counseling and psychotherapy represent different worldviews. Each theory was developed within a specific cultural context and represents the biases of that culture in trying to understand clients and facilitating change. As a result, counseling encourages therapists to view the individual in the context as well as to comprehend psychological theories within their own cultural context.

Because of Ivey's pioneering work, the centrality of culture has been widely accepted in the counseling literature. Ivey's legacy will continually impact the field of counseling psychology for generations to come.

## KITCHENER, KAREN STROHM (1943– )

---

Karen Strohm Kitchener is recognized internationally for her contributions to the fields of counseling psychology and higher education. Among counseling psychologists, she is best known for her work in ethics. In higher education, Kitchener is best known for her research on reflective judgment, the process by which people become increasingly able to draw conclusions about problems that do not have right or wrong answers (called *ill-structured problems*). Kitchener's work spans more than 3 decades and includes over 60 refereed articles and book chapters, over 30 presentations, and over 35 invited lectures, workshops, and consultations.

Kitchener was born in Toledo, Ohio, in 1943 and spent much of her childhood moving from place to place as her father moved up in his career. Although her father's ambitions for her were limited to secretarial work, Kitchener earned a bachelor's degree in history from the University of California, Santa Barbara, a master's degree in education from Claremont Graduate School, and both master's and doctoral degrees in counseling psychology from the University of Minnesota. Kitchener noted that it was during her tenure as a junior high school teacher that she decided students needed counseling more than they needed a good teacher. This realization led her to pursue a master's degree in counseling, as she intended to serve adolescents in this capacity. However, after Kitchener received her master's degree in counseling, her husband, Richard F. Kitchener, obtained a faculty position

at Colorado State University (CSU) as a professor of philosophy, and Kitchener took a position with the CSU counseling center. This position proved to be a turning point in Kitchener's career. James C. Hurst, the director of the counseling center, encouraged her to conduct research as a part of her job. This led Kitchener to conduct studies with Hurst on how to encourage faculty to use groups more effectively in the classroom. Kitchener was also influenced by Carole Geer, a counseling center staff member, who encouraged Kitchener to earn her Ph.D.

During her time at Minnesota, Kitchener participated in a seminar focused on college student development led by her chair, Clyde A. Parker. Participation in this group was another turning point, because it sparked her interest in the cognitive development of students and introduced her to Patricia M. King, with whom she would collaborate for over 30 years. Kitchener and King's participation in this group led to the development of a model of reflective judgment (based on William Perry's model of college student development). Their model focused on the intellectual development of young adults that involved changes in epistemological assumptions and how these changes affect making judgments about ill-structured problems. Kitchener and King's reflective judgment model describes seven stages of development and provides suggestions about how to assist students' progress through these stages.

Kitchener has continued to refine the reflective judgment model with King and has also jointly developed instruments (Reflective Judgment Interview and Reasoning About Current Issues Test) to assess the development of reflective judgment. Their model and

subsequent instruments have been so successful that several universities now use them as a way to effectively enhance undergraduate curricula and to assess student development.

Clearly, Kitchener has made significant contributions to the area of intellectual development. However, she has also been one of the most influential individuals in the area of ethics in counseling psychology, which is not surprising considering that many ethical dilemmas are also ill-structured problems.

Kitchener became interested in ethics when she took her first academic position in the University of Denver's Human Development Counseling Program. After she was hired by the dean, James Davis, he asked her what she would do to improve the program. Although Kitchener thought this was a strange question to ask an assistant professor, she informed Davis that she envisioned changing it to an American Psychological Association (APA)-accredited counseling psychology program. Davis agreed that this change would be beneficial, and in Kitchener's third year she was appointed director of the program. During the process of preparing for APA accreditation, Kitchener realized that the department needed to offer an ethics course. However, her husband (who also worked in ethics) suggested that ethics was not a well-developed area in psychology. As she was unable to find any other psychologist who felt competent enough to teach an ethics course, she took it upon herself to develop a course based on *Principles of Biomedical Ethics* by Tom Beauchamp and James Childress.

Over the last 30-plus years, Kitchener has conducted research and written on a variety of topics in ethics (e.g. multiple relationships, post-therapy relationships, supervision, ethical issues when working with clients who have HIV/AIDS, student affairs). These efforts have led to numerous conference presentations and invited workshops. In addition, an entire issue of *The Counseling Psychologist*, for which Kitchener served as the guest editor, was devoted to the topic of ethics. This led to the eventual publication of Kitchener's book, *The Foundations of Ethical Practice, Research, and Teaching in Psychology*, which is now used by many departments as the textbook for their ethics courses. Finally, Kitchener served as the ethics consultant and coauthored 12 of the chapters in *Ethics in HIV-Related Psychotherapy*.

In addition to her extensive research and writing on ethical issues, Kitchener has also shaped the field through professional leadership positions she has held. As examples, Kitchener served as the chair of the Ad Hoc Task Force on Ethics for Division 17

(1984–1985), was a member of the APA Ethics Committee (1985–1988) and chaired this committee from 1987 to 1988, was a member of the Ethical Principles Revision Subcommittee for APA from 1985 to 1989, and chaired this committee from 1985 to 1986. In addition, Kitchener was a member of both the Educational and Policy Task Force on Ethics for APA and the State of Colorado Mental Health Grievance Board from 1991 to 1994. Through these appointments Kitchener was able to help shape how the fields of psychology and higher education conceptualize ethics. She helped psychologists realize they had to be able to reason through ethical dilemmas and arrive at defensible conclusions. In addition, she emphasized the importance of teaching these skills to students, noting that the field changes faster than the code can be updated and that the code cannot cover every issue that a psychologist may encounter. Kitchener's influence not only shaped the way psychologists thought about ethics but also influenced the literature on ethics. As a result of her work, many textbooks on ethics now include sections on problem solving that instruct readers on how to reason through the ambiguity that is inherent in ethical issues.

It is clear Kitchener's research on and service in intellectual development and ethics have influenced the fields of counseling psychology and higher education. She has been recognized for these many accomplishments. For example, in 1983 she received the Ralph Berdie Memorial Award for outstanding research on college student development from the American Association for Counseling and Development, and then in 1991 she received the University Lecturer Award from the University of Denver for her research. In addition, she was awarded both the Contribution to Knowledge Award (1992) and the Senior Scholar Award (1993–1998) from the American College Personnel Association for her work on ethics and reflective judgment. Kitchener was also recognized in 2006 by the Colorado Psychological Association primarily for her lifetime work on ethics. She was presented with the organization's first Lifetime Achievement Award.

Although Kitchener has significantly enhanced the field of counseling psychology through her work on both reflective judgment and ethics for more than 3 decades, her contributions are far from over. Kitchener is an emeritus faculty member at the University of Denver and is currently working with her husband on a book chapter that will explore the philosophical foundations of ethical decision making in social science research. Kitchener also lectures on what it

takes to become an ethical professional. In addition to Kitchener's continual work in ethics, she also publishes in the area of reflective judgment.

Kitchener's work has served to significantly improve the fields of counseling psychology and higher education. She has been an inspiration to many because of her groundbreaking efforts, tireless approach to research, and her passion for making a difference. When you consider these qualities, it is not surprising what she has been able to accomplish or what she will continue to accomplish as her career continues. Kitchener's persistence and commitment to excellence has enabled her to become a true pioneer and serve as a role model for many psychologists, educators, and students.

---

## LEARNING DISORDERS

---

Learning disorders (LD) refer to patterns of cognitive strengths and weaknesses in individuals that may create a risk for difficulties in learning specific skills. For example, an individual with weak verbal ability may not be efficient at remembering words, resulting in a reading problem, even though the same individual may have strong visual-spatial skills, which result in good performance in math or science. Conversely, an individual with high verbal ability may be good at reading, history, and so on, but if the same individual is weak in visual-spatial ability, he or she may have difficulties with math or map reading. Thus, LD occurs when a specific cognitive weakness creates a specific deficit in an academic learning area. Although LD was originally related to academic learning, it has now also been associated with nonschool learning (e.g., driving, sports) and social learning problems.

There are two primary reasons LD has become increasingly important to the field of counseling psychology. One relates to the secondary effects of having an LD, such as the emotional frustration of a child who can't keep up in school, and the other relates to the primary late effects of LD, such as an adolescent experiencing difficulty in college or an adult with a language problem experiencing communication problems with a spouse. Children with LD often experience frustration due to school learning problems, which may create low self-esteem, emotional difficulty, and behavior problems, which in turn may create family and parenting difficulties. It is important for counseling psychologists to understand LD in

order to be able to assist parents, the child, and the family in dealing with the consequences of LD in family interactions. Another reason counseling psychologists need to have knowledge of LD is that many vocational, social, emotional, or marital problems are related to the problems in living experienced by the adolescent or adult with an LD. For example, a husband, who may have had a language-based LD in school, may have received reading assistance and no longer has a reading disability, but may still lack efficiency in the use of language. The wife may perceive that this husband ignores her because he does not communicate with her.

Counseling psychology, as a profession, has been a strong advocate for understanding and sensitivity to individual differences as well as to group differences such as gender, ethnicity, culture, and socioeconomic level. Greater knowledge of learning disorders will allow counseling psychologists to understand cognitive differences of individuals with LD and how counseling strategies may be altered in order to take into account the individual's cognitive strengths and weaknesses. It is also important for the counseling psychologist to understand LD subtypes, because many children and adults with LD deny their disorder and need counseling in order to gain better self-awareness, so they can learn to manage and compensate for their LD.

As an example, individuals with a memory deficit LD (MemLD) may not compensate by using note reminders and a calendar if they do not have insight into their LD. Their forgetfulness will create negativism from friends, teachers, parents, and colleagues. A counseling strategy that uses cognitive strengths to overcome the memory deficit may be very helpful to

this individual. Individuals with language deficit LD (LangLD) may have a tendency to become frustrated or angry when they do not understand others and do not have insight into their LD. A counseling strategy that capitalizes on this individual's strong visual-spatial skills may help this individual process information visually through pictures and maps rather than through weaker language skills. Individuals with nonverbal learning disorders (NLD) have deficits in visual-spatial skills, and hence do not often read the nonverbal cues in human interaction such as facial expression, body language, and postures denoting certain moods. Therefore, the individual with NLD may appear insensitive or naïve to others. A counseling strategy that helps this individual to learn how to verbally interpret nonverbal social communication cues may improve the social adaptability of the client with NLD.

This entry addresses three primary types of LD (MemLD, LangLD, NLD) and provides information regarding the primary social, behavioral, and emotional characteristics of each subtype as well as the cognitive patterns found through neuropsychological assessment. It also addresses the counseling implications for each subtype at elementary age, adolescence, and college age.

## Learning Disorder Subtypes

### ***Memory Deficit Type (MemLD)***

This subtype may involve weaknesses in understanding meaningful information within context (sentences, stories), more isolated information (numbers, specific words), or verbally mediated recall even when stimulus and response are nonverbal. This deficit may be more apparent in serial-order memory tasks than in memory span tasks per se, although weaknesses in both are possible.

Assessment of memory deficits typically includes tasks that measure sequential recall (involving both visual and verbal tasks), memory for increasingly longer and more complex verbal information (sentences), and nonsequential (rote) memory across multiple trials.

The most common problem for individuals with MemLD involves short-term automatic memory weaknesses for isolated (less meaningful) information. This is often apparent in digit span recall tasks. Individuals may perform better on sentence memory tasks if they possess intact associative language skills because of the semantic-associative links embedded

within this more meaningful information. Typical daily problems might involve recalling the names of people with whom they are less familiar, phone numbers and addresses, and lengthy directions or instructions that have been verbalized to them. Early academic difficulties often involve learning the names of letters and numbers as well as letter-sound associations. Difficulty with the rapid retrieval of common, well-rehearsed information is also a common problem.

### ***Language Deficit Type (LangLD)***

This subtype can involve mixed receptive and expressive weaknesses that may vary in severity. Evaluation has to be sufficiently comprehensive not only to demonstrate receptive weaknesses but also to determine whether adequate nonverbal skills exist in order to differentiate this disorder from mental retardation and pervasive developmental disorder. LangLD individuals often have difficulty understanding and following directions and expressing themselves in both verbal and written work. These symptoms can lead to being mislabeled as attention deficit hyperactivity disorder (AD/HD) due to perceived "inattention" and "off-task" behavior.

LangLD individuals with associative weaknesses often show deficits on all associative language tests regardless of whether test items are presented visually or verbally. A few LangLD individuals with intact short-term memory skills may perform well on naming or memory tests. Most perform poorly on labeling and retrieval (memory) tests and show low scores on verbal IQ subtests and on broader indices of verbal intelligence and memory. The most common problems for individuals with less severe LangLD involve school learning (particularly language-based subjects such as reading, language arts, and written expression skills). With stronger nonverbal abilities, math is often a relative strength. Problems associated with memorizing multiplication tables and basic math facts, as well as with comprehending word problems, can also be experienced. For individuals with LangLD who exhibit more severe language deficits, in addition to more pronounced school learning difficulty, significant behavioral and emotional problems are often encountered. These symptoms likely reflect deficits in communication skills and in verbal mediation, which can impair ability to exert self-control or to self-monitor behaviors. This inability to learn and understand how

to interact with others can lead to social isolation or significant social interaction difficulties.

### ***Nonverbal Learning Disorders (NLD)***

The NLD subtype often involves deficits in visual-spatial reasoning, organizational skills, time management, motor skills, and social interaction skills secondary to social perception. Deficits are manifested in school performance difficulties resulting from lost or late assignments, poor handwriting and composition weaknesses, social acceptance issues, and difficulty understanding math concepts.

Assessment of nonverbal deficits typically involves tasks that include spatial-perceptual reasoning, perceptual-motor and fine motor skills, visual processing speed, and nonverbal (associative) categorizing skills. An appropriate evaluation should also include assessment of verbal intellectual abilities, from which a developmental discrepancy can often be seen. However, recent findings have demonstrated that symptoms of NLD can be present in the absence of a discrepancy between verbal and nonverbal IQ scores.

This subtype is often misunderstood and misdiagnosed by teachers, parents, and well-intentioned professionals. The nature of this misunderstanding arises from the assumption that individuals with capable reading ability, good communication skills, and strong language learning skills do not have a “learning” disorder. Therefore, their apparent school performance difficulties must be volitional and must be related to motivation and effort.

As a consequence, individuals with NLD are often labeled as underachievers. These individuals’ weaknesses in discerning subtle nonverbal social cues (facial expression, body language, and posturing) often cause social interaction difficulties that can result in being ostracized by peers. In a desire to be better liked or more accepted, the socially naïve NLD individuals are at increased risk for social exploitation and social isolation. Although NLD was relatively unknown twenty years ago, the considerable work by Byron Rourke and others has created improved understanding and acceptance of this disorder.

### **Social, Behavioral, and Emotional Aspects**

The relationship of cognitive strengths and weaknesses to social-emotional behaviors is a growing

field of study. Recent research has shown that there are neurocognitive patterns that place individuals at risk for specific social-emotional disorders dependent upon the interaction of the neurocognitive pattern with environmental conditions.

### ***Memory Learning Disorder (MemLD)***

The short-term memory problem of individuals with MemLD can create confusing perceptions by others such as parents, peers, teachers, or spouses. Individuals with MemLD typically have good long-term memory and associative language skills. Therefore, others perceive them as adequate or even bright in verbal language skills. So when they forget simple information, others may assume they were not listening, they did not care what the other person was saying, or they may have attention deficit disorder.

Young children with MemLD will often have symptoms that may help to identify them. They may show difficulty remembering the names of common objects, have difficulty remembering numbers and letters, and may forget even simple directions. Parents often interpret these symptoms as willful neglect or attention deficits. Children who otherwise appear cognitively alert but show these symptoms often have an undiagnosed memory disorder. There is research to show this is a relatively common condition in males and often runs in families. Although specific genetic studies have not isolated specific genes, population genetic studies have shown the male familial incidence.

Memory problems during adolescence are often attributed to bad attitude and lack of caring. When school problems first arise in adolescents, many assume this is due to willful neglect of homework. When adolescents do not follow directions of parents, it is often assumed this is due to rebellion. However, it is important to first rule out a short-term memory deficit before making these assumptions. Often the adolescent with MemLD has been able to “get by” in school due to good language skills; however, as the amount of content to be studied increases in junior high or high school, there is a greater load on memory, and difficulties arise. Also, many adolescents would rather appear to have a motivational problem than be identified as having a learning problem. Research has shown that most attention deficits are identified prior to adolescence, so if an adolescent suddenly shows signs of attention deficit disorder, the counseling psychologist should be alert for a possible memory deficit.

College students who have never shown previous difficulty in learning and then begin to struggle academically often have a memory deficit. Individuals with MemLD usually learn to read, especially if they have received strong early phonics instruction. However, they usually read at a slower rate than average as they attempt to comprehend and remember what they have read. The increased reading demands in college often expose this slow reading rate and the student is not able to keep up. Also, the memory deficit will make it difficult for the college student to listen and remember multiple lectures throughout the day. As they try to take notes, they cannot remember what the instructor is saying. These symptoms should alert the counselor to the possibility of a memory-based learning disorder.

### **Language Learning Disorder (LangLD)**

There is some disagreement in the literature regarding how to classify the various types of language disorders. Some consider the memory disorder discussed in the previous section as a form of an expressive or verbal language disorder. In this section, the discussion will be limited to an associative language disorder that is referred to by some as a *receptive language disorder* or a *comprehension language disorder*. There is considerable evidence that children with language disorder are at risk for behavioral and emotional disorders.

The primary problem for the individual with an associative language disorder is a deficiency in efficient verbal mediation skills necessary for verbal abstract reasoning and the self-verbal guidance needed for self-control and maintenance of attention and behavior. This may result in comprehension deficits in academic learning, inability to form the verbal abstraction necessary to develop complex interpersonal relationships, and difficulty in governing externalization of thoughts, feelings, and behavior.

Young children with a language disorder may experience chronic school failure, social rejection, and low self-esteem. They may not have the verbal flexibility to engage in social or teasing banter often seen in young children, and, therefore, they may be ostracized from playgroups. They do not have the verbal fluency to rapidly answer a question in class, so the teacher may cease to call on them. They often perform poorly on tests that tax their verbal comprehension ability. The response to this constellation of

problems is social withdrawal, dislike of school, and sometimes acting out behavior due to frustration. These children are often seen as having a primary behavior disorder and are punished, or they are seen as having AD/HD and are medicated.

During adolescence, youth with LangLD often begin to become so frustrated due to school failure and lack of positive peer groups they are at risk for bullying or joining unsavory peer groups. Because they do not have efficient verbal abstract reasoning skills, they are vulnerable to the influence of others and are often set up by other behavior-disordered peers to be the scapegoat for group problem behaviors. As academic functioning becomes more abstract, they may drop out of school or attend alternative school for behavior disorders. There is a critical period for language development change with early language therapy success, but not at this age. At this point, recognition of the LangLD can at least lead to functional educational intervention, vocational rehabilitation training, and counseling strategies, which all rely more on visual and active interventions rather than verbal strategies.

Individuals with LangLD rarely succeed academically at a level that will be found in traditional universities. However, they may be attending junior college, vocational schools, or colleges for students with LD.

### **Nonverbal Learning Disorders (NLD)**

The primary characteristic of the individual with (NLD) is difficulty processing visual-spatial information despite good verbal reasoning and verbal memory functions. The cognitive aspects of this problem lead to difficulty with schoolwork involving written work, worksheets, map reading, note taking, and other visual integration tasks. Difficulty in visual abstract reasoning also may result in problems with conceptual elements of time management and organization. A further problem for many individuals with NLD relates to social interaction skills. Individuals with NLD often have difficulty interpreting the nonverbal aspects of human interaction. They have difficulty with reading body language, facial expression, and tone of voice, for example, anger versus joy.

The younger child with NLD usually shows both school and social difficulties. Due to delay in development of visual-spatial and visual-motor skills, they may have school difficulty such as messy worksheets and handwriting problems. The primary academic

difficulty is usually in math because of the visual-spatial aspects of mathematical thinking. However, because individuals with NLD usually have good verbal skills, they are often successful in most academic areas. One difficulty often encountered is that teachers and parents may think that these children are not trying on written work or in math because they do so well in other subjects. It is important for the counselor to recognize that the combined symptoms of math problems, messy schoolwork, and social perception concerns may indicate a NLD.

Adolescents with NLD often show organizational difficulties characterized by unfinished or lost schoolwork, decline in scores on long standardized tests, and math difficulties. Also adolescents with NLD may begin to become involved with problem peer groups as an attempt to find social interaction, because they are often ostracized from mainstream peer groups. As some adolescents with NLD begin to act out due to social frustration, they are often misdiagnosed as having AD/HD or behavior disorders. However, careful examination of the etiology of these behaviors often reveals a frustrated, lonely adolescent who lacks the social skills necessary for positive social interaction.

College students with NLD are at particular risk for emotional difficulties. They have often been successful academically, so they may not have experienced particular problems if they have been protected from social difficulty by parents and family. However, when they leave home, there is increased pressure to develop independent social functioning, and their social perception concerns may impair their ability to have positive peer groups or social interactions. This may lead to serious feelings of social isolation, and due to their good verbal abstract reasoning skills, they are also at risk for the loneliness of existential self-questioning. College counselors need to recognize the symptoms of NLD in the students they encounter, because there are academic modifications that can be made and therapeutic approaches to address the self-insight needed to overcome NLD.

### **Counselor Implications**

When working with individuals with LD, counseling psychologists may need to use techniques that fit with the individual's cognitive strengths and focus on certain types of behaviors that relate to the LD. As with any intervention, these techniques will be different for different age groups.

### ***Elementary Age***

Counseling psychologists will often be working with parents as much as children in this age group. Strategies that are concrete and do not involve abstract thinking are often needed when working with elementary age children.

#### **Memory Learning Disorder (MemLD)**

Teaching elementary age children specific memory strategies, such as mnemonic devices, acronyms, and verbal cumulative rehearsal, can be helpful. In addition, instructing parents on adding external memory devices, such as using lists and bulletin boards, may be a good strategy.

#### **Language Learning Disorder (LangLD)**

Children with LangLD may have a difficult time expressing themselves verbally, so behavioral techniques or strategies that allow them to express themselves through play, pictures, or music may be helpful.

#### **Nonverbal Learning Disorder (NLD)**

Social skills training is often needed with elementary age children with NLD. This training should be very explicit and outline specific steps in social interaction and nonverbal communication. Modeling and role-playing is often beneficial. Elementary age children with NLD often do not intuitively pick up social skills, so explicit instruction is helpful.

### ***Adolescent Age***

In adolescence, more individual work with the adolescent and less involvement with the parent begins to take place, and new strategies may be needed. At this age, helping to determine what impact (if any) the LD is having in the adolescent's life may be a focus of counseling. In addition, addressing some of the specific social, behavioral, and emotional aspects of the adolescent's LD may be necessary.

#### **Memory Learning Disorder (MemLD)**

As with elementary age children, teaching specific memory strategies would continue to be helpful, with the adolescents beginning to use external memory devices themselves. At this age, individuals can learn

more abstract memory strategies, such as using associations and stories during counseling.

### Language Learning Disorder (LangLD)

Incorporating visual and active strategies can be helpful for adolescents with LangLD. Helping them recognize the impact of the LangLD in their social relationships and everyday life and teaching coping strategies may be a focus of counseling. It may also be helpful to involve parents in counseling, so that they may also learn how to better communicate with their adolescent.

### Nonverbal Learning Disorder (NLD)

Social skills training will likely continue to be a key component in counseling for adolescents with NLD. As with elementary age students, teaching these skills explicitly is ideal. Adolescents may also need help with general organization strategies.

### College Age

College age individuals are working on transitioning to being independent and responsible for everyday life. They will likely participate in counseling by themselves and have minimal parental support.

### Memory Learning Disorder (MemLD)

Teaching memory strategies will continue to be important at this age, again focusing on external memory devices. If students have good associative skills, teaching them how to make associations and use stories can be a useful strategy.

### Language Learning Disorder (LangLD)

As with other age groups, college age individuals with LangLD would benefit from using visual and active techniques in counseling. Traditional talking strategies may be difficult and cause frustration for individuals with LangLD. A focus of counseling should include how their LD has an impact on relationships with significant others and strategies to improve all types of communication, both verbal and nonverbal.

### Nonverbal Learning Disorder (NLD)

Again, social interaction difficulties are prominent with college age individuals with NLD. In addition to

social skills training, counseling may need to focus more on relationships rather than just skills. Counseling psychologists may also need to help the college age individual with NLD explore the impact NLD has on his or her daily life, including academic and social areas.

## LEGAL ISSUES IN PARENTING

---

The legal issues regarding parenting can be, and often are, highly complicated and controversial issues, needing to be addressed within the following categories: custody, adoption, parenting by unmarried couples, and rights and responsibilities of parents.

Understanding how these variables interact is important, because many individuals experiencing problems in their relationships will seek help through counseling. If mental health professionals continue using the same therapeutic tools common in the past, then it is possible that the counselor may harm the client; for example, what an unmarried, heterosexual couple faces is likely to be different from what an unmarried, same-sex couple might experience.

## Custody

When a couple becomes divorced and children are involved, custody is an inevitable issue. There are two kinds of custody: legal custody and physical custody. *Legal custody* refers to the fact that all major decisions are made by the individual(s) with legal authority to decide, based on the best interests of the child. Within legal custody, there are two types: sole legal custody and joint legal custody. Sole legal custody states that only one parent possesses the legal authority to make major decisions on behalf of the children. These resolutions are focused upon education, religion, and health care. On the other hand, joint legal custody refers to the fact that both parents possess the same legal authority to make decisions on behalf of the children. These decisions may include the type of education the children receive, type(s) of religion (or lack thereof) the children will be raised within, nonemergency medical decisions, etc.

*Physical custody* refers to a legally binding decision as to where the children reside for the majority of the time. Again, within this custody are three categories: sole physical custody, joint physical custody, and bird's nest custody. *Sole physical custody* means the children live with one parent at one physical location most of the time. Generally, the noncustodial parent follows a *visitation schedule* (in some states, the term is *parenting time*, *alternative placement*, or a *parenting schedule*) allowing for generous visitation rights; that is, the children may sleep over at the noncustodial parent's house. *Joint physical custody* is also called *shared custody*, *shared parenting*, or *dual residence*. With joint physical custody, each parent lives with the children for a specific part of the week, month, or year—the times and the length depending upon parental agreement. Normally, the children spend approximately the same amount of time with each parent. *Bird's nest custody* means the children reside at one central location, with the parents taking turns to move in and

out of the children's residence on a previously agreed schedule.

Almost all divorcing parents choose shared parenting (joint physical custody), because it is the closest facsimile to the original parent-child family structure. Meanwhile, the law considers either joint legal custody or joint physical custody as the best custody option when both parents are deemed fit to raise the children. Another primary reason for the attractiveness of joint custody is that any major decision affecting the child is made by both parents—both parents must agree to any action involving the children.

Empirical studies support shared parenting as the most suitable arrangement, because it has the most positive impact on the children. For instance, children in joint custody are less likely to have behavioral or emotional problems and appear to have higher levels of self-esteem, better family relations, and better academic performance when compared to children in sole custody arrangements. In fact, the concept of shared parenting or joint custody was first developed in 1970 for the primary purpose of helping both parents be equally involved in raising their children. Courts have preferred joint custody since it was first used in Indiana in 1973. However, some studies argue against shared parenting, stating it is the reflection of a predivorce family structure; thus, there should be caution against an uncritical acceptance of the idea that the husband and wife make identical contributions to parenting.

Another issue seldom involved in custody agreements is the payment of child support. The law treats child support and visitation as separate issues. In other words, even if a parent fails to pay child support, he or she may not lose visitation rights.

## Adoption

There are four major types of adoption proceedings:

1. *Individual adoption* refers to a single person making a decision to adopt a child, once a child's biological parents have terminated their parental rights by their free will. The adoption decision is made based on the best interests of the child. Thus, prior to approving the adoption, a home study is conducted. During this period, scores are given to the potential adopting parent based on several factors, such as parenting skills, income, physical and mental health, and so on.

2. *Joint adoption* refers to a child being adopted by both parents who have had no previous biological or adoptive relationships with the child. The procedure is similar to individual adoption, i.e., a home study is conducted to assess whether adoption is in the best interests of the child. Most states do not approve of adoptions if both parents are of the same sex. However, exceptions do exist, such as Pennsylvania and Iowa.

3. *Second-parent adoption* allows a same-sex partner in a relationship to adopt the legal child (biological or adoptive) of his or her partner. For gays and lesbians, second-parent adoption is the only legal method that ensures their legal rights and responsibilities with respect to their partner's child. Moreover, second-parent adoptions protect children in lesbian and gay families by giving them the security of two legal parents.

This is not to say, however, that the child's other biological parent "disappears"; rather, second-parent adoption is only viable if the second biological parent agrees to terminate his or her parental rights. If no consent for termination is given, then any adoption is considered illegal and subject to both civil and criminal law. Sperm donors usually terminate any and all parental rights to any children conceived once their sperm has been donated.

The following conditions are created in second-parent adoption: (a) If the biological parent dies, the second-parent's custody right is guaranteed; (b) the child becomes the recognized heir to the second parent; and (c) the child is eligible for the second parent's health benefits as well as other benefits, such as social security survivor benefits when the second parent dies.

4. *International adoption* refers to individuals or couples adopting children outside their own nation. When an American or an American couple decides to adopt a child from another country, the adoptive parents have to comply with American adoption laws (federal and state) as well as the law of the child's birth country. Adoption laws in most foreign countries do not allow gay/lesbian or unmarried couples to adopt children.

### Parenting Issues for Unmarried Couples

When unmarried heterosexual couples have children, it is essential that both parents be recognized as the child's legal parents, because it bestows upon the

child certain rights, for example, rights of inheritance, social security benefits, child support, health coverage, etc. In addition, lawyers recommend that both parents make a formal, written contract stating their intention to continue coparenting, even if their relationship with one another is terminated.

For unmarried couples, only one parent can claim the child as a dependent for tax purposes. With regard to medical care, when biological parents share custody of a child, they are the only people vested with the legal authority to make medical decisions for the child. On the other hand, if one biological parent is not involved, then the partner of the other biological parent may be listed as the emergency contact person for the child; however, the involved biological parent has the first choice in making any medical decisions.

### Rights and Responsibilities of Parents

By law, parents are legally responsible for their children until the children reach the age of majority, and in most countries, this occurs when the child reaches 18. Meanwhile, the law allows parents certain rights with respect to important decisions regarding different aspects of their children's lives, such as education, religion, and so on. Most of the time, the law does not interfere in parents' decisions unless the child's life is threatened or in extreme situations, for example, if the parents ignore their children's needs for medical care. In fact, parental prosecution has occurred in cases where parents, following their religious beliefs, refused to allow their seriously ill children access to appropriate medical treatment.

The law also requires parents to restrain their children's behavior. For example, if a child damages someone else's property, the parents are responsible. In addition, if a parent is deemed incompetent in terms of controlling his or her child's behavior and the child's behavior is seriously out of control, the law has the right to intervene, that is, to take custody away from the parents until the situation has improved.

## LOW-INCIDENCE DISABILITIES

---

Definitions of disabilities categorized as low-incidence vary in scope. Broadly defined, low-incidence disabilities refer to a visual impairment or hearing loss, deaf-blindness, and significant cognitive impairment. For children, the definition extends to any impairment that requires individualized intervention services provided by professionals with highly specialized skills and knowledge in order for the child to benefit from his or her education. Thus, this definition includes individuals with autism, traumatic brain injuries, orthopedic impairments, or multiple disabilities. Although these classifications may be useful for data collection or communicating potential needs of clients with a particular disability, individuals within each disability category may be more different than they are alike and will likely require highly individualized services.

Even when a very broad definition is used, individuals with low-incidence disabilities compose a small percentage of the population. Nevertheless, it is likely that counselors will encounter clients with low-incidence disabilities in their practice. Individuals with disabilities, like all individuals, may present with a variety of physical, social, and psychological needs that may warrant professional intervention. In keeping with ethical standards, professionals should practice within the scope of their training and recognize when it may be more appropriate to refer to a practitioner with specialized training in the area of the client's disability.

This entry focuses primarily on issues related to providing services to individuals with visual impairments, deaf-blindness, and hearing loss.

### Understanding Low-Incidence Disabilities

#### *Deaf/Hard of Hearing*

Within the medical field, hearing loss is typically defined by one's ability to perceive sounds of different frequencies and at different intensities. Hearing loss is classified as normal (0–15 decibel [dB] loss), mild (26–40 dB loss), moderate (41–70 dB), severe (71–90 dB), or profound (91 dB or greater). In addition, hearing losses may be classified as conductive, sensorineural, mixed, or central auditory processing disorders. Hearing loss can also be defined by functional ability. For example, individuals who are able to communicate using the telephone are often considered "hard of hearing," while those who primarily receive information visually rather than through auditory pathways are considered "deaf." These medical and functional definitions do not necessarily correspond with an individual's cultural identity. Some clients who have a hearing loss may consider themselves culturally Deaf (indicated with the capital *D*), reflecting their pride in belonging to a community of individuals that share common experiences, a rich cultural heritage, and a shared language—sign language.

The deaf and hard of hearing population is heterogeneous. Factors to consider when working with an individual who is deaf or hard of hearing include the cause, type, severity, and stability of hearing loss; age of onset; type of amplification preferred; preferred communication modality; presence of any additional disabilities; and cultural affiliation. The unique interplay of these factors differentially impacts the individual's language development, speech intelligibility, academic performance, self-concept, identity, behavior, and social and emotional development.

#### *Visual Impairment/Blindness*

Definitions of visual impairment vary but often refer to levels of visual acuity or functioning. Clarity of vision is typically defined in terms of visual acuity, measured on a scale comparing the person's vision at 20 feet with that of someone who has full acuity. Visual acuity ranges from normal vision (20/20

acuity) to profound low vision acuity (lower than 20/400). Visual acuity that approximates total blindness may also be designated by functional descriptions such as the ability to detect light. The term *blindness* typically refers to total vision loss, including no light perception, or significant impairment in sight, making it necessary for the individual to rely primarily on senses other than vision to interact with the environment. *Legal blindness* does not necessarily imply total blindness, and it is defined as corrected distance visual acuity of less than 20/200 or a visual field of 20 degrees or less in the better eye. Individuals with visual impairments demonstrate a wide range of vision functioning that may fluctuate on a daily basis due to a variety of factors.

Factors contributing to the uniqueness of each individual with a vision loss include the type, severity, etiology, age of onset, and stability of the vision impairment as well as the presence of one or more developmental disabilities.

### **Deaf-Blind**

Individuals who are considered deaf-blind have co-occurring vision and hearing losses. The vision and hearing loss both may have been present from birth, or one may precede the other. Often, vision and/or hearing may decline throughout the individual's lifetime. Clients fitting this classification likely have significant impairments in vision and hearing, requiring specialized services that are not adequately defined by typical services for individuals who are either deaf or blind. Vision and hearing functioning vary considerably within this population, resulting in varied communication preferences and use of assistive devices. Thus, factors contributing to the uniqueness of individuals who are deaf-blind include the etiology, age of onset, severity of visual and hearing impairment, communication preferences, and presence of comorbid disabilities.

## **Counseling Considerations**

### **Cultural Perspective**

The mental health needs of individuals with low-incidence disabilities have been traditionally underserved. Historically, counselors' misunderstandings about individuals with disabilities often led to erroneous assumptions that clients with significant hearing and/or vision loss lacked the language and

cognitive skills necessary to benefit from therapy. Clients with disabilities who continually encounter bias in their everyday lives may be resistant to or distrustful of counselors who they do not feel relate to their experience. Furthermore, limited accessibility to services continues to be influenced by the shortage of professionals trained to meet the unique needs of these clients. In particular, there is a scarcity of practitioners who can communicate directly with clients using sign language.

### **Communication**

Because of the importance of communication in therapy, it is critical for counselors to attempt to match the client's preferred mode of communication. Clients who are deaf, hard of hearing, or deaf-blind may prefer to communicate using speech, American Sign Language or other sign language systems, cued speech, gestures, pantomime, body language and facial expressions, writing, or combinations of the above. Communicating directly with clients in their preferred mode of communication is preferable to facilitate the therapeutic process. However, when direct communication is not possible, counselors may have to rely on using interpreters. Counselors should be aware of the impact of indirect communication on the therapeutic relationship with their client, including the client's level of trust and confidence in the counselor, the increased likelihood of miscommunication, and challenges in effectively assessing the client's language level and thought process. When interpreters must be used, it is preferable to use a consistent, certified interpreter.

### **Developmental Perspective**

A developmental perspective is also important when working with clients with low-incidence disabilities. For example, young children with visual impairments will need support to learn how to explore and function independently within their environment. Severe visual impairment may affect children's social skills. They may need to be directly taught skills for using meaningful gestures and appropriate facial expressions, joining in sports and other social activities, assertiveness, and self-advocacy. Children with congenital blindness may also demonstrate behaviors that appear to be autistic (e.g., echolalia, stereotypic behaviors), which may also interfere with socialization.

Language delays associated with hearing loss may also significantly affect one's behavioral regulation and

social skills throughout the life span. Children with hearing loss may feel isolated from peers who do not use the same communication modality. Adapting to their hearing and/or vision loss may have a significant impact on individuals' developing sense of identity and willingness to assert their independence. Individuals coping with sudden or progressive vision and/or hearing loss may benefit from counseling as they adjust to resulting changes. Even those who have seemingly adjusted to the impact of their vision loss may re-experience social and emotional adjustment difficulties when faced with particular developmental milestones impacted by their visual impairment, such as getting a driver's license or transitioning to college or the workplace.

### ***Ecological Perspective***

When working with clients with low-incidence disabilities, it is important for counselors to consider the match between the client and his or her environment, given each client's unique characteristics and needs. It may be particularly important to include families in counseling. Much like individuals reacting to progressive vision or hearing loss, parents go through a process similar to grieving in reaction to their child's diagnosis. Particularly when the diagnosis is made during early childhood, parents' attachment and parenting skills may be affected. The overwhelming majority of children who are deaf are born to hearing parents. This results in a unique situation in which the child may communicate using a language that differs from his or her parents' language and may identify with a culture that differs from his or her parents' hearing culture. Furthermore, an individual's declining vision and/or hearing functioning also likely has an impact on the family. It may be beneficial to include other family members in treatment to address changes in roles and responsibilities and associated stress on the family unit.

### ***Role of the Counselor***

Counselors fill a variety of roles working with clients with low-incidence disabilities. Rehabilitation counselors evaluate and address clients' independent living skills, use of assistive devices, social interaction skills, academic or career skills, and recreation and leisure skills. An assessment of language and communication functioning or orientation and mobility skills may also be warranted.

Professionals conducting assessments with individuals with low-incidence disabilities should refer to

professional guidelines regarding appropriate assessment procedures. Assessment tools must be selected carefully with the understanding that few instruments allow comparisons with other individuals demonstrating similar disabilities. When working with clients with visual impairments, clinicians should avoid tasks that place heavy demands on vision, including verbal tasks with a corresponding visual component, unless the purpose of the assessment is to measure vision. Conversely, when working with clients with hearing loss, nonverbal, performance-based tasks may yield the best estimate of functioning. It may be appropriate to provide accommodations during the assessment that facilitate the client's access to the tasks without significantly altering the construct intended to be measured. One should also take into consideration whether the assessment reflects experiences that may be outside of the client's repertoire due to the impact of the vision or hearing loss. Finally, the impact of vision or hearing loss on processing speed, concentration, attention, and fatigue should be carefully considered when interpreting results.

## MEDIATION

---

Mediation is a type of intervention meant to reduce or eliminate conflict among persons or parties who have opposing desires in a situation. For example, a family mediator may assist a couple going through a divorce to reach an agreement on the terms of the divorce in areas such as custody of children, settlement of property, and so on. More technically, mediation is the intervention by a third party who is acceptable to the disagreeing parties, who is impartial, and who is neutral (having no relationship with the disagreeing parties). Neutrality also means that the mediator will not gain personal favors or benefits from one of the parties for assisting with mediation.

By definition, mediation is part of *negotiation*. That means that mediation occurs during a process in which two or more people or parties are discussing their differences and attempting to reach a solution on one or more areas of disagreement. Mediation, therefore, is an extension of negotiation with the addition of a third, neutral party in the negotiation discussions. The assumption behind the addition of the mediator is that the third party will be able to influence the relationship between the two disagreeing parties in such a way as to help them settle the disagreement. The mediator might, for example, balance a power differential, influence the behavior of one of the parties, create a more effective problem-solving process, or create a more facilitative atmosphere during the discussions.

The mediator does not have the power to make a final decision in the disagreement. A judge or an arbitrator may be designated by law or procedure to make

a final decision in favor of one or the other party or partially favoring both. In contrast, a mediator assists the parties in arriving at a mutually acceptable solution that maximizes each party's interest.

Mediation has gained favor in recent years as a method of conflict resolution, because it offers several benefits. When compared to litigation, mediation can result in quicker and less expensive decisions. If completed successfully, mediation, by definition, results in a decision that maximizes each party's interest and thus should be more satisfactory to both parties than a decision arrived at by a judge or arbitrator. Mediation can consider a variety of issues between parties, including ones not typically considered in courts. Last, and of interest to counselors, mediation can teach the parties more effective skills of negotiation and problem solving, which can be applied in future disputes.

Mediation proceeds along a series of stages. These stages begin with initial contacts with the parties to the dispute and continue through assisting the parties in selecting a strategy to work with during mediation, collecting background information, defining the issues and setting the agenda, generating options for the agreement, conducting final negotiations, and achieving a settlement. Within each of these stages are various tasks for mediators and parties. For example, during initial contacts with the parties, the mediator will be working to prepare the parties to work together cooperatively, defusing negative emotions resulting from previously unsuccessful negotiations, building trust, clarifying expectations, and ensuring clear communication.

There are three terms that are central concepts for mediation: issues, interests, and positions. *Issues* are the topics or problems that the mediator and the

parties will focus on during their discussion. For example, divorcing parents may identify issues of child support, custody, and spousal relocation. A community that is divided over location of low-income housing may identify issues of distribution versus proximity, distribution among schools, and closeness to appropriate services.

*Interests* are the needs that each party wishes to satisfy and thus are much less easily communicated than issues. For example, in a divorce case, a husband may have a need to have continuing communication with his children even though his wife may be awarded custody. Other interests, such as having one's point of view heard fully, achieving a cooperative solution, avoiding emotional blow-ups that endanger future relations, and feeling respected during the negotiation process, are ones that each party may feel comfortable discussing with the mediator but not with the opposing party. However, the mediation must meet these needs in order to be successful.

*Positions* are proposals or ideas of solutions that either party is putting forward to meet their interests and needs. For example, with divorcing parents, a position is "I want joint custody." Another position is "I want the children all summer, because you will be the primary custodial parent." In a community struggling over low-income housing location, one position might be "We want all this housing to be located in one area, because distributing such housing around town will lower property values." Another position might be "Our community is a caring community, and every neighborhood should have a certain number of low-income housing units." Because positions are framed from each party's view, they are usually going to be one-sided and favor one party over the other.

The mediator's task, therefore, is to reframe positions so that both parties move from bargaining over positions to discussing interests. As an example, a mediator might ask why a certain position (e.g., joint custody) is important for the party. Redefining the problem as one in which the solution needs to satisfy the interests of both parties, rather than the positions, is another way for the mediator to move from positional bargaining to mediation. Reframing the mediation process from arguing over positions to discussing and considering needs and interests is critical to the success of the mediation. Most likely, the previous negotiations have already exhausted the discussion of the positions, and thus the mediator needs to exercise certain skills to move the parties' discussions into new ground.

At the conclusion of the mediation, the mediator plays a critical role. Once settlement options have been discussed, the mediator will carry out many tasks. One task is that of testing reality for both parties: Will this settlement meet your needs and interests? Another task is helping both parties consider long-term as well as short-term impacts of the settlement options. A third task is for mediators to assist the parties in comparing settlement options to other alternatives.

Mediators typically have received specialized training. Counselors might consider whether learning mediation skills and adding mediation to their skill set is a way of expanding their practice and invigorating their typical work. Many of the microskills that a counselor is already effectively using—empathic communication, recognizing feelings, relabeling, reframing, containing difficult client emotion—are ones that are essential to successful mediation.

## MEDICATION ADHERENCE

---

The phrase *medication adherence* refers to the extent to which persons given a pharmacologic treatment actually use it in the way the prescribing clinician intends, for example, taking an antibiotic twice every day with a 12-hour interval between doses. Medication adherence is a complex phenomenon related to characteristics of the person using the medication, his or her beliefs about it and its effectiveness, the milieu in which he or she lives, the characteristics of the treatment

(frequency of doses, presence of side effects), and external mechanisms used to remember to take medication, such as pill boxes or automatic reminder devices. Park has argued for the integration of these areas in a broader model for understanding medication adherence.

### **Person Characteristics**

Several characteristics of the person prescribed a medication may affect his or her adherence to its use. Cognitive function, mood, age, socioeconomic status, and cultural background are all related to medication adherence. Poorer cognitive function has been related to lower levels of adherence, and more complex cognitive functions such as executive abilities may be related to more complex adherence behaviors. Depression has a negative effect on adherence. Although increasing age is commonly thought to be associated with poorer adherence, several studies have shown that older adults actually have better adherence than their younger counterparts. African Americans have been shown to have poorer adherence to some medications even after controlling for factors such as access to care and socioeconomic status.

### **Person Beliefs**

Individuals' beliefs about the medication, including the extent to which it is useful for the condition for which it is given, have important effects on adherence. Several theories have been proposed to explain the relation between beliefs and behavior, including Janz and Becker's health belief model and Ajzen's theory of planned behavior as well as others. In addition to beliefs about effectiveness, beliefs about the seriousness of the treated condition can affect adherence. Adherence to a medication believed to be ineffective or prescribed for a condition that is viewed as not very serious (e.g., a medication for mild insomnia) is likely to be lower than for an effective medication given for a life-threatening condition.

### **Treatment Characteristics**

Characteristics of the treatment regimen may also affect adherence. Regimen complexity (number of medications, number of doses, whether doses must be taken a certain time before meals or should be taken with food) plays a role in adherence. In some health

conditions, such as HIV-related diseases, regimen complexity may interact with cognitive status. The presence or absence and severity of adverse effects (side effects) have an important negative impact on medication adherence.

### **Social Environment**

Beliefs of caregivers, significant others, or family members about the medication's effectiveness and the condition for which it is prescribed are likely to affect adherence. Caregiver or family beliefs may be especially important for conditions that affect cognitive or functional status and thus require external information or caregiver interventions (e.g., Alzheimer's disease, congestive heart failure, HIV-related dementia).

### **External Supports**

Individuals' medication adherence is a complex behavior that must occur over long periods of time. Maintenance of the behavior consistently over such intervals can be supported by mechanical devices such as pill boxes that can be filled a week or month at a time and thus provide passive prompts to the treated individual on a daily basis. Active prompts can be provided via alarm clock-based timers, computer-based automated reminding via home telephones or pagers, and in-home checks and reminders by home healthcare workers.

### **Importance**

Medication adherence is vitally important in the treatment of disease. To the extent that a condition is affected by medication, adherence to the regimen may be critical and even life sustaining. An example of the critical importance of adherence is provided by the effects of adherence on antiretroviral treatments for HIV infection. High levels of adherence are required for successful suppression of viral replication and improved immune system functioning. Importantly, intermittent or low levels of adherence may result in the creation of medication-resistant viral strains. Adherence is related to likelihood of hospitalization in some conditions, such as congestive heart failure, where close adherence to treatment can affect the status of the cardiovascular system. Medication adherence has been related to various healthcare outcomes, including medication adverse events, hospitalization, and healthcare costs.

Perhaps most interestingly, high levels of adherence are related to healthcare outcomes independent of other treatment interventions. Studies show that high levels of adherence even to placebo may be associated with better health outcomes than intermittent adherence to active medication. A review of these studies has led some to propose a “good adherer” type that may be associated with a variety of healthcare behaviors such as diet and exercise. According to Joynt and colleagues, it is likely that medication adherence and other behaviors interact with physical disease factors to produce good or poor healthcare outcomes.

### Interventions to Improve Adherence

Each of the areas associated with medication adherence has been the target of interventions to improve adherence. Interventions that target persons’ beliefs about medication effectiveness and condition seriousness have been useful in improving adherence, especially when the messages are made personally relevant to the person taking the medication. Family or social milieu interventions may also be effective in improving adherence. Changes in treatment characteristics, such as minimizing regimen complexity and reducing the impact of adverse medication effects, can improve adherence. External supports or reminders, whether passive or active, are also effective in improving medication adherence. Computer-based interventions may become increasingly important in improving medication adherence, because they can make labor-intensive interventions, such as providing individually tailored information, economically feasible.

## MENTAL HEALTH ISSUES IN THE SCHOOLS

---

School mental health programs and services in the United States have grown rapidly, facilitated by the recommendations of important initiatives such as the U.S. Public Health Service, 2000; the President’s New Freedom Commission on Mental Health, 2003; and the American Academy of Pediatrics Committee

on School Health, 2004. Schools offer access as a point of engagement with youth to address their academic and mental health needs; school mental health programs and services offer potential for reduced stigma for help seeking, increased generalization and maintenance of treatment gains, enhanced capacity for prevention and mental health promotion efforts, and ecologically grounded roles for clinicians.

School mental health is an emerging field with challenges confronted at many levels. Figure 1, an adaptation of a template proposed by Weist, Paternite, and Adelsheim and first published by Flaspohler, Anderson-Butcher, Paternite, Weist, and Wandersman, presents interrelated actions to support policies, infrastructures, resources, and practices to strengthen effective school mental health. Desired outcomes include student emotional and behavioral well-being and school success as well as enhanced family, school, and community systematic functioning. To achieve these outcomes, effective mental health promotion, primary and secondary prevention, assessment and early intervention, and intensive treatment programs and services are needed.

Undertaking a critical quality assessment and improvement agenda, in which delivery of culturally competent evidence-based practices are reflective of strong family and community engagement, helps to ensure effective school mental health practices. Service delivery infrastructures that reflect effective communication, strong collaboration, and meaningful training underpin the successful development and implementation of such programs and services. Policies that are based on a clear understanding of the current status and needs of the field promote effective school mental health practices and inform strategic planning. Judiciously allocated resources support well-coordinated, nonduplicative school mental health programs and services that reflect a common agenda for families and other stakeholders in child-serving systems (education, mental health, health, child welfare, and juvenile justice).

This entry presents several key themes for the advancement of school mental health. These include the importance of and challenges associated with achieving conceptual clarity about school mental health, the need to prioritize preventive services and mental health promotion, the move toward mental health and education systems integration, the need to strengthen the research base of the field, and future directions of school mental health.

## **Achieving Conceptual Clarity About School Mental Health**

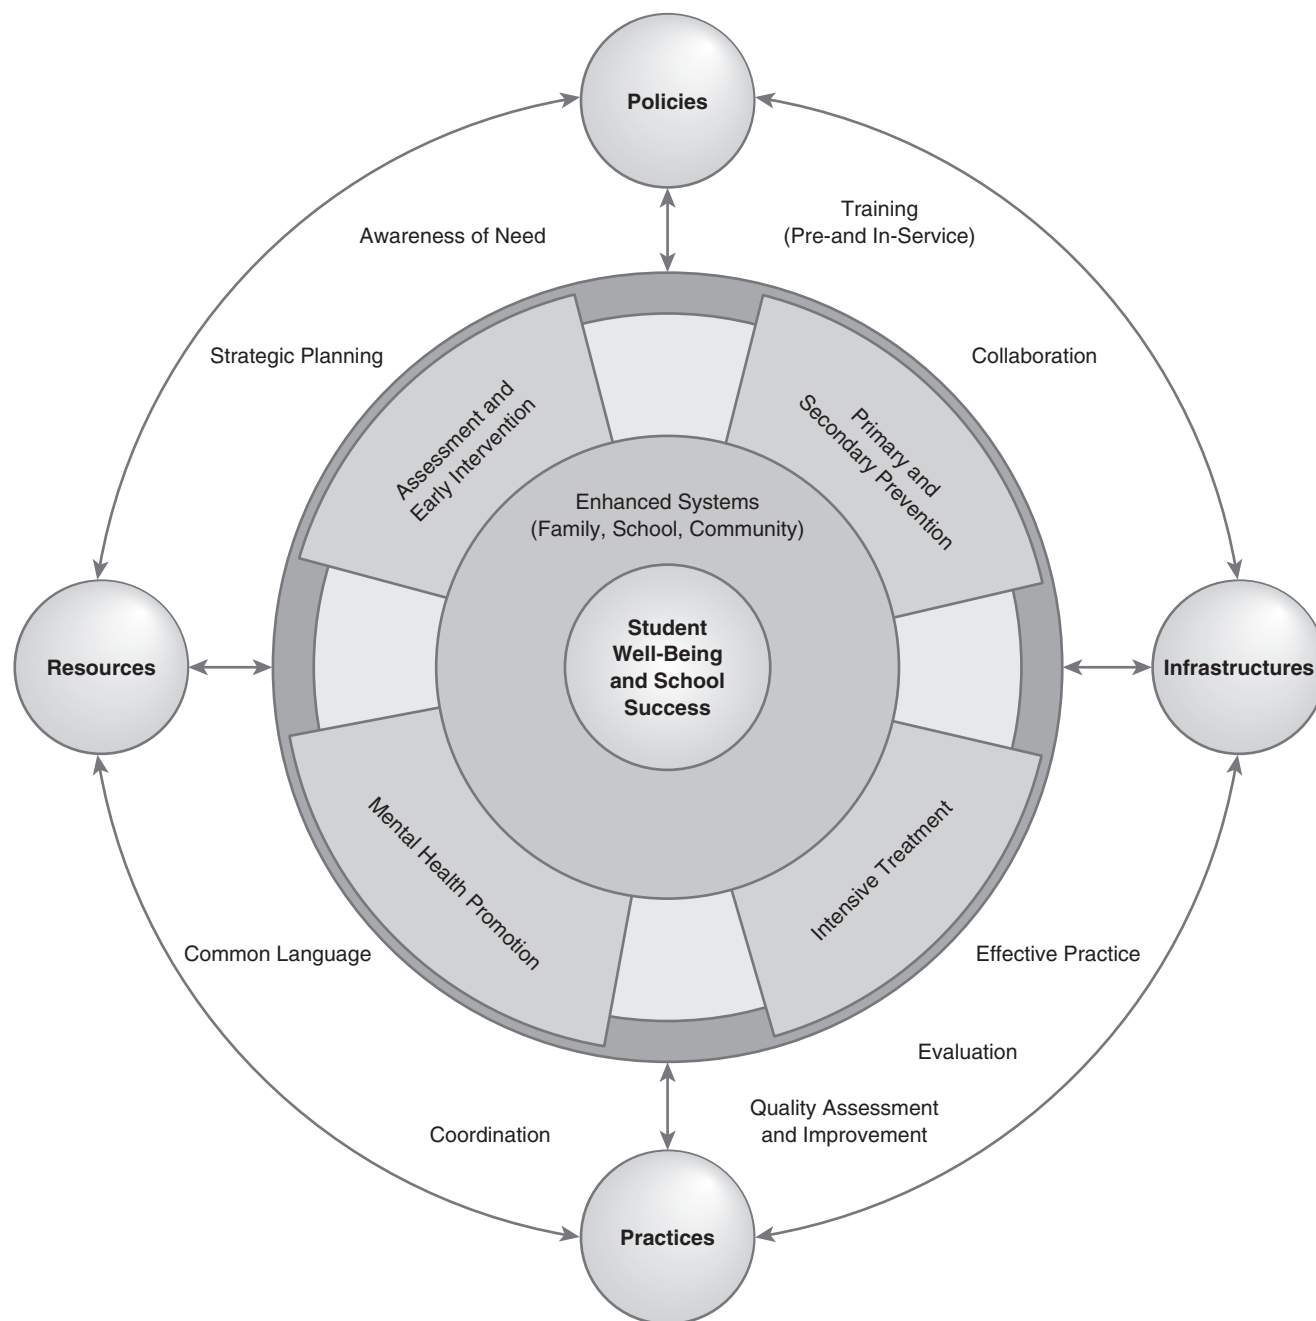

School mental health services have been delivered in a variety of forms, and there is not an explicit best practice model. However, the term *expanded school mental health* describes programs and services that incorporate key elements reflected in the recommendations of the President's New Freedom Commission on Mental Health, 2003 and other important initiatives referred to above. These elements include the following: (a) family-school-community agency partnerships; (b) commitment to a continuum of mental health education, promotion, assessment, problem prevention, early intervention, and treatment; and (c) services for youth in general and special education.

*Expanded* conveys building on programs and services that exist in most schools, including the work of school-employed staff (e.g., school psychologists, social workers, counselors, school nurses, and teachers with behavioral expertise). The emphasis on effective collaboration between schools and community entities (e.g., mental health centers, health departments, university-affiliated centers) is based on the realization that schools cannot do all the work alone. Often, schools are overburdened with demands that could be addressed by other community systems. A strong connection between schools and community organizations also helps a community move toward a system of care. Expanded school mental health is a framework within which other critical elements are essential, including interdisciplinary collaboration, family and other stakeholder engagement, ongoing quality assessment and improvement, culturally competent services, and empirically supported practice.

## **Prioritizing Preventive Services and Population- Focused Mental Health Promotion**

An essential intent of expanded school mental health is to contribute to the creation of a comprehensive and integrated system of support and care for youth, which necessitates attention to the promotion of healthy development and to primary-through-tertiary prevention of problems in their own right and as significant barriers to school success. One of the realities of delivering mental health services in schools is that providers find it hard to remain committed to a full spectrum of

**Figure 1** Conceptual framework for action to advance school-based mental health

*Source:* Adapted from Flaspohler, Anderson-Butcher, Paternite, Weist, and Wandersman (2006).

activity. Without diligence about preventive and mental health promotion efforts, drift can occur easily toward primarily individual services for students with severe or chronic problems. In part, this is due to a fundamental bias that undergirds how “mental health” is approached in the United States. Training, service delivery

approaches, and fee-for-service funding are focused primarily on treating disorders that are presumed to exist within individuals, and school staff contend with a flood of referrals for students with serious problems and crises, making the implementation of preventive and health-promoting services difficult. For school

mental health in everyday practice in the United States, the World Health Organization model of health-promoting schools, emphasizing population-based health promotion at the base and treatment for youth with serious problems at the apex, essentially is inverted.

Advocates for school mental health services emphasize the importance of prioritizing prevention and mental health promotion. For example, Atkins and colleagues have documented effective strategies for adapting school mental health programs to the needs and competencies of teachers, parents, and students to capitalize on schools' unique opportunities to provide mental health-promoting activities. Clearly though, there is need for individual intervention in a school mental health program; however, that place should be circumscribed and informed by the evidence in support of its use.

In embracing the shift necessary to move toward enhanced preventive services and mental health promotion, examples from other countries are instructive. Australia, Cuba, and many Western European nations are prioritizing mental health promotion strategies for all youth in schools. In addition, important international groups are advancing the dialogue about school mental health promotion, such as the Clifford Beers Foundation, the World Federation for Mental Health, the International Union for Health Promotion and Education, the Society for Prevention Research, and the International Alliance for Child and Adolescent Mental Health and Schools.

### **Promoting the Integration of Mental Health and Education Systems**

Historically, school mental health programs and staff (e.g., social workers, psychologists, counselors) often have been considered by educators to be "add ons." The seeming incompatibility between the "nonacademic" interests of mental health providers and the "academic" interests of educators has resulted, at best, in uneasy cooperation. Adelman and Taylor and others have suggested that the mental health and education systems move beyond program cooperation and strive for program integration—with mental health staff and educators working together closely based on shared values and goals.

Several strategies promote the integration of mental health and education systems, including the following: (a) ensuring strong collaboration among families, school leaders, and mental health leaders in

program planning; (b) ensuring that school mental health providers understand school cultures and how to work as collaborative partners and that they are well trained, closely supervised, and interpersonally skilled; (c) ensuring that school mental health practices are of high quality and are empirically supported; (d) emphasizing school mental health services as effective means for reducing barriers to learning and promoting school success; and (e) documenting that services lead to outcomes valued by youth, families, and schools. Much of this work addresses the need to achieve in-depth understanding of schools—the people who live and work in them (especially teachers)—from multiple perspectives.

Although schools cannot be held responsible for meeting every need of every student, most educators endorse an educational agenda that involves enhancing academic skills and physical, social, emotional, and character development. In addition, many professionals advocate that schools address student needs that directly affect learning and school success. There is compelling evidence that emotional and behavioral health problems are significant barriers to learning and that there are strong positive associations between mental health and academic success.

If schools do not have expanded school mental health services and programs, linkages to community-based services can be employed, but these linkages generally are quite poor or nonexistent. In addition, in the absence of the expanded approach, there often is "tier drift" into special education, with excessive referrals in order to give students access to mental health services. This practice results in increased burdens to special education systems, often for services of questionable value for youth who might not truly have learning impairments. Alternatively, if schools embrace movement toward expanding mental health services, the challenge of enhancing integration of mental health and education systems is complex. There are many issues to be addressed, such as the following:

1. Who will the community partners be and how will their work be integrated with the efforts of school-employed mental health and educational staff?
2. How will broad stakeholder perspective be incorporated into the program model?
3. How will a full continuum of services be guaranteed?

4. How will ongoing training needs of personnel be addressed to ensure that they have the competencies needed to collaborate successfully and to deliver effective services?
5. How will the quality of service delivery be assessed along dimensions meaningful for all stakeholders, and what strategies will be used for promoting empirically supported practices?

### Strengthening the Research Base

In spite of strong momentum to promote enhanced mental health practices in schools, the research base for school mental health is quite limited. Much current research is focused on development and delivery of evidence-based child mental health services. However, the impact of this research on everyday practice in community settings, and in schools, is restricted.

The promotion of effective mental health practices in schools involves more than simply trumpeting the selection of evidence-based approaches, most of which have not been examined for their effectiveness, palatability, durability, affordability, sustainability, and transportability in and to real world school or clinic settings. In addition, the dearth of research on diffusion, dissemination, and the processes of change in movement toward effective mental health practices all contribute to the continuing gulf between evidence-based and current, everyday practice. The literature on evidence-based practices in children's mental health does not typically attend to features of the school context that influence intervention delivery.

The community science model proposed by Wandersman and the deployment-focused model of intervention development and testing proposed by Weisz and colleagues both emphasize that practice-based evidence is an untapped resource in the development and delivery of effective school (and community-based) mental health services. Both models highlight the significance of and variability across everyday clinical practice conditions.

Wandersman proposed a "community science," a multidisciplinary field that attempts to strengthen community functioning by investigating how to improve the quality of common approaches (health promotion, education, prevention, treatment) implemented in real world settings. Community science emphasizes community-centered models to complement

the research-to-practice model that serves as the dominant paradigm for the development of best practice programs. Community-centered models focus attention on local needs, see best practice as process rather than magic bullet programs, and emphasize control by practitioner, client, or community. Key attributes of community-centered models also include emphasis on local evaluation and self-monitoring and on a research agenda that focuses on tailoring interventions to fit local needs and contexts.

In short, community science promotes local participation oriented toward accountability in the community delivery *process* (rather than just proven intervention content delivered with fidelity). Engaging practitioners in planning, implementing, evaluating, sustaining, and continuously improving prevention, risk reduction, and treatment efforts based on locally determined needs builds local capacity to improve the quality of practice and achieve positive health outcomes.

Even with evidence-based school mental health practices that have been shaped along dimensions noted above, successful implementation depends on many systemic factors, such as the support of school staff, negotiation of obstacles such as time in the curriculum, and school day and space. Efforts to promote evidence-based school mental health must be imbedded in a broader, ongoing commitment to quality assessment and improvement. However, systematic research and practice on quality assurance have been limited in school mental health. Currently, Weisz and colleagues are studying school mental health quality assessment and improvement (QAI) programming at sites in three states. For the study, they developed the School Mental Health Quality Assessment Questionnaire, which assesses 10 principles for best practice in school mental health (see Table 1). An important goal of the study is to promote evidence-based structuring of the school mental health "independent variable," which has important implications for developing a credible services (practice-based) research agenda for the school mental health field.

### Future Directions

With progressive development over the past two decades and significant recent support from federal initiatives, school mental health is becoming a force in the United States. Increasingly, communities are turning to school mental health to improve inaccessible

**Table 1** Ten principles for best practice in school-based mental health

1. All youth and families are able to access appropriate care regardless of their ability to pay.
2. Programs are implemented to address needs and strengthen assets for students, families, schools, and communities.
3. Programs and services focus on reducing barriers to development and learning, are student and family friendly, and are based on evidence of positive impact.
4. Students, families, teachers, and other important groups are actively involved in the program's development, oversight, evaluation, and continuous improvement.
5. Quality assessment and improvement activities continually guide and provide feedback to the program.
6. A continuum of care is provided, including schoolwide mental health promotion, early intervention, and treatment.
7. Staff hold to high ethical standards; are committed to children, adolescents, and families; and display an energetic, flexible, responsive, and proactive style in delivering services.
8. Staff are respectful of and competently address developmental, cultural, and personal differences among students, families, and staff.
9. Staff build and maintain strong relationships with other mental health and healthcare providers and with other educators in the school, and a theme of interdisciplinary collaboration characterizes all efforts.
10. Mental health programs in the school are coordinated with related programs in other community settings.

and ineffective youth mental health systems and to assist families and schools in addressing youth mental health, which is inexorably linked to academic success. However, school mental health is an emerging field, and an integrated strategy is needed to advance policy, increase resources, improve training and support to programs and staff, emphasize quality and evidence-based practices, and document outcomes—in promotion of a true public mental health agenda.

Related to federalism (states' rights, local control), limited focus on health promotion and problem prevention, and inadequate access to care, the United States has not embraced a public health promotion agenda for any health condition, including emotional and behavioral health of children and adolescents. However, the President's New Freedom Commission on Mental Health, the first presidential initiative addressing mental health in 30 years, provides an historic opportunity for the advancement of a public mental health promotion agenda, with school mental health a cornerstone. The final report of the commission focused on transforming mental health care in America and emphasized a specific recommendation to "expand and improve school mental health programs." This recommendation, based on consensus of diverse national experts, provides sanction and credibility for federal- and state-supported and

locally driven efforts to bring effective mental health promotion to youth where they are.

delay in reaching certain developmental milestones that typify the normally developing person. Mental retardation (MR) is a developmental disability that is exemplified by the presence of deficits in both *cognitive* and *adaptive* functioning. Individuals with MR have significantly limited patterns of personal functioning, though these patterns will vary from person to person, depending on the severity and type of deficits. As with any developmental disability, the limits in functioning of an MR individual are manifest by infancy or early childhood and are lifelong in nature.

## The Nature of Mental Retardation and Developmental Disabilities

### Diagnostic Criteria

The diagnostic criteria for MR are listed in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)* under the heading of “Disorders Usually First Diagnosed in Infancy, Childhood, and Adolescence” and can also be found in the American Association on Mental Retardation's (AAMR) *Mental Retardation: Definition, Classification, and Systems of Supports, Tenth Edition*. (Note: The AAMR has changed its name to the American Association on Intellectual and Developmental Disabilities.)

To warrant a diagnosis of MR, both of the following symptoms must be present in an individual prior to age 18: below average intellectual functioning and impairment in at least two areas of adaptive functioning.

Intellectual functioning is assessed using standardized instruments that measure an individual's intelligence quotient (IQ), such as the Wechsler Adult Intelligence Scale—Third Edition and the Stanford-Binet Intelligence Scales, Fifth Edition. Standardized IQ scores exist along a normal continuum, where a mean IQ score of 100 (standard deviation of 15) reflects an individual with average intelligence. To be considered for an MR diagnosis, individuals must have an IQ score approximately two standard deviations below the mean. This means that an IQ score of approximately 70 or below is needed to demonstrate significantly subpar intellectual functioning. Moreover, intellectual functioning is also coded to reflect the severity of impairment: mild (50–55 to approximately 70), moderate (35–40 to 50–55), severe (20–25 to 35–40), and profound (20–25 or below). Unspecified is the code given when there is a strong suspicion of MR, but actual IQ scores cannot be determined due to

---

## MENTAL RETARDATION AND DEVELOPMENTAL DISABILITIES

---

*Developmental disability* is an umbrella term that broadly refers to a set of severe and chronic physical or mental impairments characterized by an absence or

factors that interfere with IQ testing, such as uncooperativeness or extremely impaired functioning.

*Adaptive functioning* refers to activities needed to successfully navigate day-to-day demands of life. When individuals exhibit adaptive functioning deficits, they display consistent ineffectiveness in completing these daily activities. Levels of adaptive functioning are considered in light of the chronological age of an individual and are measured using standardized assessment instruments, such as the Vineland Adaptive Behavior Scales, Second Edition and the AAMR Adaptive Behavior Scale, Second Edition. The broad areas of adaptive functioning considered for an MR diagnosis include daily living skills, communication skills, and social and interpersonal skills. *Daily living skills* refer to a set of behaviors that center on self-care, household chores, work or academic involvement, and the ability to access community resources. *Communication skills* involve the ability to accurately understand others and express oneself. Social and interpersonal skills are the set of skills needed to successfully interact with others, cope with daily stressors, and make use of free time. In addition to these three areas, deficits in fine and gross motor skills, such as toilet training and walking, may also be assessed in children.

In addition to intellectual functioning and adaptive functioning, the AAMR definition of MR goes a step further and integrates a skills-based component to shift the focus away from the solely limitations-based definition given by the *DSM-IV-TR*. For example, the AAMR definition of MR addresses the context of the individual's limitations, strengths, and available environmental supports. Both the *DSM-IV-TR* and the AAMR suggest that before a diagnosis of MR is rendered, it is imperative to rule out medical conditions, cultural and language considerations, and physical limitations (e.g., hearing or visual impairments) that may interfere with normal development or current functioning. In addition, developmental issues should be taken into account when assessing adaptive functioning; for example, it would be inappropriate to measure occupational performance when assessing the adaptive functioning of a child.

## Causes

A variety of genetic, chromosomal, and environmental causal sources have been linked to MR. Genetic and chromosomal disorders are thought to account for approximately half of MR cases, with the other half due to environmental or unknown causes. Examples of

genetic and chromosomal types of disorders include the following: metabolic disorders (e.g., phenylketonuria, galactosemia) and chromosomal abnormalities (Down syndrome, Klinefelter's syndrome, fragile X). Environmental causes include chronic and severe neglect of basic needs (e.g., food, affection), teratogen exposure in utero (e.g., fetal alcohol syndrome, Food and Drug Administration pregnancy category D- and X-classed drugs), fetal and infant malnutrition, and birth complications (e.g., hypoxia, premature delivery).

## Morbidity

Most reliable sources, such as the Centers for Disease Control and Prevention and the AAMR, put the prevalence rate of MR at about 1% to 3% of the general population. The incidences of MR caused by genetic and chromosomal factors occur similarly across different socioeconomic categories. Environmental causes (e.g., lead poisoning and malnutrition) appear to occur more commonly in individuals of lower socioeconomic status. In addition, MR seems to occur at a higher frequency in males (1.5 males to 1 female). Mild MR is more common, representing approximately 85% of all individuals in this group. Moderate MR occurs at 10%, severe MR corresponds to approximately 3% of all MR cases, and profound MR occurs in approximately 1% of such individuals. In general, people with MR have the same rates of chronic physical and mental health disorders as the general population. The exceptions are due to the problematic symptoms specific to certain disorders, such as metabolic disorders, and with the neurological abnormalities and physical limitations present in individuals with profound MR.

## Changes and Challenges

### Treatment Interventions

Interventions for MR individuals directly target adaptive living skills and take into account both the limitations and strengths of the individual. Interventions typically address increasing self-determination, targeting problematic behaviors, increasing social skills, and assisting caregivers, families, and employers in modifying the individual's environment to maximize success. This is best accomplished by coordinating several services, such as therapy, vocational rehabilitation, social services, schools, and caregivers. Interventions are highly dependent on the individual's level of disability; for instance, a treatment plan for an individual with mild

MR will be different from that for an individual with more extensive limitations. A typical example of an individual with mild MR might be a day school program that places academic lessons in the context of daily living, such as focusing on social skills, reading bus schedules, calculating a simple budget, cooking, and household upkeep. Vocational training is also a recommended treatment consideration and should be based on the individual's strengths.

In addition, healthcare providers are increasingly aware that psychological disorders occur at a much higher rate in the MR population than previously thought and warrant psychological services. Rates of depression, anxiety, conduct problems, or impulse control issues are common, and, consistent with the symptomatology of these disorders, injurious behaviors are sometimes present. Interventions targeting these behaviors are important, as is teaching beneficial coping mechanisms (e.g., time-out/taking a break, redirecting attention). Likewise, the appropriate use of psychotropic medication can be a viable treatment avenue. Insight-oriented therapy may have some utility with individuals with mild MR. Therapeutic interventions should focus on modeling healthy emotional expression, managing interpersonal and professional relationships, and managing stressful situations.

### Caregiver Issues

According to the AAMR, trends indicate a four-fold decrease in the number of MR individuals in state institutions over the past 30 years. This transition out of institutions into residential settings has been beneficial for many MR individuals, as it promotes self-determination, yet this trend has increased stresses for caregivers and families in several ways. The additional emotional and social supports needed to care for MR individuals can be difficult to understand by all members of the family, particularly for siblings. Financial hardship induced by the unique needs of MR individuals can be taxing. Though many MR individuals are recipients of Medicaid benefits that decrease the financial burden of health care, there is often difficulty finding physicians who will take Medicaid patients, because reimbursement rates are lower than those provided by other types of health insurance. Physical demands are placed on caregivers and families. Activities such as lifting or transporting the person with MR or dealing with injurious or other challenging behaviors can increase stress and fatigue. Nonprofit

organizations that assist families with these demands are invaluable, as they help with issues such as finding community resources, transportation, and respite care. Many of these organizations, however, have extensive waiting lists. Paid caregivers are typically reimbursed for their services at a low rate, generating high turnover and poor continuity of care. In general, stress and fatigue can prompt an increase in abusive and neglectful behaviors among caregivers. Such behaviors can be either passive (e.g., failure to respond to basic needs) or active (e.g., physical violence, verbal abuse). Regardless, attending to the psychological needs of the caregivers of MR individuals and providing social supports are important intervention considerations.

## MENTORING

---

Mentoring is an activity or relationship that occurs between two or more persons interested in advancing their knowledge, skills or position via a helping relationship. A *mentoring relationship* is one in which a more skilled or knowledgeable person assists another

who possesses less knowledge and/or skill in a particular area. These relationships typically last beyond a single encounter and can be either formal, informal, or some combination of the two. By definition, mentoring begins as a hierarchical relationship in which the mentor and protégé engage in a variety of roles and functions to support the protégé's learning and development. Most mentoring relationships follow a predictable path and over time develop into a more collegial relationship that allows for reciprocity and mutuality between the mentor and protégé. Although, the concept of mentoring can be traced back to Greek mythology, no systematic studies of mentoring were conducted until the early 1970s.

### A Brief History of Mentoring

Mentoring relationships have been documented in the literature since antiquity. The first use of the term *mentor* is credited to Homer in his third book of the *Odyssey*. In this Greek myth, Odysseus, a great royal warrior, calls upon his friend Mentor to serve as a guide and advisor to the entire royal household when Odysseus leaves to fight the Trojan wars. Athena, the goddess of wisdom, takes the form of Mentor and accompanies and guides Telemachus, Odysseus's son, on a journey in search of his father. During this journey, Telemachus strives for and develops a new and fuller identity, hence the parallels between Telemachus's journey and that of the modern day protégé.

Mentor-apprentice relationships have also been documented through the development of artisans' guilds as a means to pass on particular skills and ways of being. In these settings, a more experienced and typically older adult educated, challenged, and supported the younger adult or protégé. The protégé remained in the mentoring relationship until he or she learned and could demonstrate the knowledge and practices of that particular craft. The practice of mentoring allowed members of guilds or professions an agreed-upon process through which they could transmit the specific technical and intellectual heritage of their discipline to selected individuals. Thus, mentoring served as means for selection, education, and continuity within professions.

### The Nature of Mentoring

Mentoring occurs along a continuum, from formal mentoring at one end to informal mentoring at the other end. The distinguishing characteristics of a

formal mentoring relationship describe the nature, purpose, duration, and quality of the contact. In a formal mentoring relationship, the mentor and protégé are typically assigned to work with each other, by a third person or group, in order to complete a specific purpose, training, or task. The mentor is clearly in charge and responsible for the work of the protégé. The mentor directs the activities without much expectation of a reciprocal relationship from the protégé. The relationship remains hierarchical, and the interactions formal. Mentoring ends when the protégé has acquired the desired skills or accomplished the specific task. Because the contact is more formal, task-focused, and shorter in duration, mentors and protégés typically do not report much interpersonal support or relational progression.

In contrast, informal mentoring relationships focus less on specific behaviors or tasks of the mentor and protégé and more on the nature, quality, and process of interpersonal and professional relationship. Informal mentoring relationships are typically initiated by the protégé for the purpose of longer-term personal and professional development. The mentoring relationship is expected to last over time and may or may not have an explicit end. The relationship begins in a somewhat formalized and hierarchical manner and progresses through identifiable stages. In informal mentoring relationships, the mentor and protégé experience intensity within the relationship that provides for reciprocity, interpersonal regard, comprehensiveness, appreciation, and gratitude.

### Stages of a Mentoring Relationship

Numerous researchers have examined the nature and process of mentoring. Kram has researched mentoring since the early 1980s. She identified four stages of a mentoring relationship that appear to be sequential and developmental. It should be noted that the stage model presented here is one of many in the literature, and there is a lack of agreement among researchers as to what defines a stage, what the duration of a stage is, and what constitutes movement within and between stages. The four stages are initiation, cultivation, separation, and individuality. The stages occur more frequently in informal mentoring relationships.

In the initiation stage, the mentor is idealized by the protégé and viewed as all-knowing. In the second stage, cultivation, the mentor provides vocational guidance and personal support. During the separation

stage, the protégé has become more competent and independent and is able to offer more to the mentor. It is also in this third stage that the mentor is more likely to experience mutuality and reciprocity with the protégé. The final stage, individuality, is defined by a sense of dichotomy. That is, the mentor and protégé either develop a mutually supportive friendship or they separate feeling used and bitter.

### Mentor Roles and Functions

Researchers have suggested that mentors engage protégés from a variety of roles and provide a number of functions. The terms *roles* and *functions* are often used interchangeably, yet scholars in the area of mentoring distinguished them as follows. Roles are a series of expected attitudes, dispositions, behaviors, and obligations organized around a specific vocation. Functions are specific behaviors or actions that emanate from specific roles.

A skilled mentor moves in and out of his or her roles effortlessly. The role adopted by a mentor is determined by the stage of the mentoring relationship and often is a blend of several roles. The adoption of a role or roles is subtle and nuanced. The mentor role is related to the perceived, identified, or expressed need(s) of the protégé. Mentor roles include: teacher, sponsor, advocate, role model, advisor, evaluator, coach, and supervisor. Knowledge, responsibility, accountability, maturity, and ethical behavior are inherent in the roles of a mentor.

In the early to mid-1980s, Kram and other researchers identified two categories of mentor functions, psychosocial and career. Psychosocial functions are personal in nature and focused on the relationship. The mentor provides acceptance, support, encouragement, advice, guidance, and challenge to the protégé. Psychosocial functions provide the foundation for the personal and sometimes intense nature of the mentoring relationship. The career or vocational functions provided by mentors provide the protégé opportunities, “plum assignments,” coaching, protection, role modeling, social status, reflected credit, sponsorship, advocacy, visibility and exposure. These functions are provided with the protégé’s career goals in mind and are related to the institution or profession in which both are currently engaged. Thus a mentor may introduce a protégé to selected influential colleagues at a conference (sponsorship and reflected credit) and encourage them to attend the protégé’s presentation (visibility and exposure). This interaction provides the protégé a role model of one engaging with professional peers and

may, in the long term, enhance the social status of the protégé. Mentor functions, like mentor role models, are complex and dynamic interactions that occur as a result of the quality and strength of the relationship.

### Benefits and Costs of Mentoring

Mentoring relationships are widely recognized as vital personal and career resources in many disciplines. Mentoring has been an essential element in the training of business professionals, nurses, psychologists, counselors, and educators. There are numerous and detailed accounts of the benefits to the institution, the mentor, and the protégé. For the institution, particularly in higher education, researchers report the benefits to be stable, enthusiastic, and productive employees; less employee attrition, lower training cost, and greater scholarly productivity. The benefits to the mentor include the development of a dependable peer-in-training; generativity or giving back to one’s profession; rejuvenation and enrichment of one’s energies, career, and research interests; and working with a person that has the potential to carry on the mentor’s legacy. Protégés benefit from greater socialization into their vocation, improved career and personal performance, higher salaries, and more frequent promotions. In settings such as higher education, protégés have reported that they experienced greater satisfaction with their graduate education, improved postgraduate scholarly productivity, and more ease achieving tenure and promotion once employed in the academy.

Despite the many benefits of mentoring, there are also some barriers or costs related to this process. Researchers have reported that institutions tend to expect professionals to accept preselected protégés without the professional’s input or to provide mentoring to junior colleagues or students without any additional release time, compensation, or resources. The lack of personal involvement and support can lead to professionals feeling confused and burdened, while protégés may be left feeling disregarded. Protégés have reported that mentoring relationships can be confusing or detrimental when the mentor engages in unethical behavior by violating either academic or personal standards of appropriateness.

## MINDFULNESS

---

Mindfulness refers to a meditative practice most commonly associated with Buddhism that dates back to 25 centuries ago as part of the Buddha's teachings. It has become increasingly popular in the Western world over the past 2 decades. Mindfulness meditation involves the practice of becoming fully aware of the present moment and all that is happening in the moment. Observations of the present moment are made without judgment, without categorization or opinion. Rather, the idea is to observe what is actually there in the moment.

Becoming fully aware of the present moment through the practice of mindfulness meditation is thought to make it possible for people to truly experience life, because life can only be found in the present moment. The premise is that individuals often spend much time thinking about the past, the future, or places other than where they actually are. Our attention is given to things that take away from our ability to accurately perceive and experience the present. Living out of the moment separates us from our experiences and makes it more difficult to deal with life in an effective and mindful fashion. Our minds are occupied by thinking, judging, worry, or other distractions, with the result that we are not being fully aware of the present. The belief is that if we are not really there (or fully present), it is difficult to see things deeply and clearly. Instead, we perceive events in a vague fashion without deep understanding. Further, by living so much out of the moment or in a mindless fashion, we are not truly ourselves. That is, by functioning with our minds elsewhere, in the past or in the future, our

body and mind are separated from each other. By practicing mindfulness in a concentrated fashion, our body and mind become one or are reunified and we become our true selves.

The ability to practice mindfulness must be learned and developed through regular practice. Certain methods are taught to develop the capacity for mindfulness, with attention to the breath being one of the most important. For example, one might pay attention to inhaling and exhaling by saying such things as, "Breathing in I know that this is my in-breath, and breathing out I know that this is my out-breath." By paying attention to breathing in and out, the individual is brought to the present moment. Distracting thoughts and emotions that divide one's attention and interfere with clear thinking and perception are removed. In a sense, everything stops, and what is left is the present moment with all of its contents. The practice of mindfulness (being in the present moment) can be done in a fashion that is traditionally associated with meditative practice. For example, it may be practiced in a quiet setting set aside as a place for meditation using specific steps designed to develop the capacity for mindfulness in an optimal fashion. However, expert practitioners of mindfulness make it clear that the practice can also be done in any daily activity such as washing dishes, driving a car, or walking.

By engaging in the practice of mindfulness, one is more prepared to deal with life's challenges. For example, if one's anger is triggered, the practice of mindfulness might be to return to breathing and say something like, "Breathing in I know that I am angry; breathing out I know that I am angry." The anger is not suppressed or avoided. Rather, it is noted or observed. There is no judgment about whether or not one should be angry, but rather, one simply notes that one is angry. Even though the anger is still there, it has already become different. The person is taking appropriate care of his or her anger by acknowledging it and looking deeply into it. This practice is thought to bring about a transformation by creating the ability to look deeply into the anger and to see the roots of it through deep awareness so that it can be released. Suffering is released through awareness and understanding. The same process is applied to other difficulties such as depression, anxiety, or other forms of suffering. Also, the practice of mindfulness is thought to allow people to realize that they are more than their sickness, more than their sorrow, more than their suffering.

Practitioners say that when fully developed, mindfulness permits people to keep themselves free of

mental barriers, to achieve liberation from their suffering, and to be less vulnerable to the ups and downs of living. The sort of deep observation produced through mindfulness is said to lead to the complete absence of confusion. Also, practitioners of mindfulness note that while peace is important, the capacity to enjoy peace is important too, and the practice of mindfulness cultivates the capacity to enjoy peace as well. Peace, happiness, and joy are said to be available in the present moment if one has the capacity to experience them.

### Current Applications to Counseling and Health

Mindfulness meditation is being used with increasing frequency in areas related to mental health. For example, Marsha Linehan has incorporated the practice of mindfulness meditation into her treatment approach, termed dialectical behavior therapy (DBT), for borderline personality disorder. Part of the approach includes what she has called “core mindfulness skills,” which are essentially techniques that make it possible for the client to become more fully aware of his or her experiences and to develop the capacity to stay with the experience in the present moment, rather than being overwhelmed or distracted by thoughts and feelings that might otherwise block progress. Mindfulness meditation is also being used in some cognitive treatments for depression.

Also, the Center for Mindfulness in Medicine, Health Care, and Society at the University of Massachusetts Medical School was established in 1995. The center has a mindfulness based stress reduction (MBSR) program, which is one of a number of successful initiatives developed to assist people through the use of mindfulness meditation. Further, The National Center for Complementary and Alternative Medicine has been funding research on the practice of mindfulness.

### Other Applications

Several other examples of the growing popularity of mindfulness meditation can be found. A number of prominent law schools are using mindfulness meditation to improve the ability to listen and function more skillfully. A notable example can be found at the University of Missouri School of Law, which has established the Initiative on Mindfulness in Law and

Dispute Resolution, which involves research, teaching in law school courses, and public service using the practice of mindfulness meditation. The practice is used to help lawyers, litigants, mediators, and others listen better, improve self-awareness and understanding of others, manage stress more effectively, and function better in general. Mindfulness meditation is also being used by some professional sports teams and some corporations.

---

## MIXED METHODOLOGY RESEARCH

---

Mixed methodology research incorporates both qualitative and quantitative research methods. Qualitative research methods provide detailed descriptions about

phenomena and may include interviews, observations, and analyses of documents, records, artifacts, photos, and film. Researchers choose this methodology when they are interested in a rich narrative description with an abundance of deep detail. Quantitative research methods, on the other hand, include randomized experimental and quasi-experimental designs, surveys, written or oral assessments, and other standardized instruments with which responses can be measured on a numerical scale. Statistical procedures are then used to analyze the numerical responses. In mixed methods research, both qualitative and quantitative methods are used in data collection or data analysis in the same study. Mixed methodologists believe that this developing paradigm will be the dominant form of research during the 21st century.

## Paradigms

The type of methodology researchers use depends on their research perspective or paradigm. Scholarly conversations in this area have been highly developed for both the quantitative and qualitative paradigms. Over the last decade, mixed methodologists have begun to add to this debate.

### Quantitative

Purely quantitative researchers generally work from the *positivist-postpositivist* paradigm. They believe that phenomena can best be measured and explained using the scientific method, which has been the dominant paradigm throughout the history of social science research. Quantitative researchers use *experimental* designs in which participants are randomly assigned to a *treatment group*, the group receiving the specific treatment, or the *control group*, which is the group not receiving the treatment. For example, in drug studies, some subjects will be randomly assigned to receive a drug and some subjects, assigned to the control group, will receive a placebo. The researchers then may administer a standardized instrument (an assessment that measures the results of the study) to both groups. Statistical analysis is conducted to compare the results.

A second type of design quantitative researchers use is the *quasi-experimental* design, which includes both treatment and control groups, but subjects are not randomly assigned to either group. Quasi-experimental designs are often used when dealing with intact

groups where random assignment is not feasible, such as classrooms of students.

A third design quantitative researchers use is the *causal comparative* design. In causal comparative studies, the researcher does not impose a treatment. Instead research is done after the fact, or *ex post facto*. The researcher looks for cause and effect relationships based on group differences. For example, the researcher might investigate how familial support among new mothers is related to their postpartum depression levels.

### Qualitative

Purely qualitative researchers work from the *interpretive-constructivist* paradigm. They believe that the way to understand phenomena is through exploring people's interpretations. Qualitative researchers use designs such as case study, ethnography, phenomenology, grounded theory, and narrative inquiry. Data collection is carried out as naturalistically as possible in the research context through the use of observations, interviews, and collection of documents and records. Some examples of qualitative research include a case study of counseling techniques at a clinic, an ethnography of a school counselor's day-to-day practice over an extended period of time, and an examination of counselors' use of intuition in a phenomenological study. While there are many detailed approaches to qualitative analysis, qualitative research is analyzed categorically or thematically; the researcher reads the data to identify similarities and dissimilarities.

### Mixed Methods

In mixed methods research, the researcher's paradigm is often *pragmatism*. Pragmatists believe not only that it is acceptable to use multiple paradigms in the same research study but that qualitative and quantitative methods can be complementary. For a mixed methodologist, "what works" becomes the driving factor. Pragmatists value both the subjective and the objective; they believe that the research question is the most important issue. The research question, not the framework, should drive the method. By combining qualitative and quantitative methods, researchers are able to discover issues that might otherwise go undetected. However, critics of pragmatism have dismissed this paradigm as naïve, simplistic, and overly applied. A mixed methodologist would contend that an undue focus on theory and paradigms has detracted

from the need to focus on the point of research: the research question. The focus on the problem and not theory is one of the reasons mixed methodology has emerged as a field that is demanding respect.

## History

Mixed methodology research has been called the third methodological movement. Mixed methods research has not always been and is not currently accepted by all research methodologists. Though it is a “new” methodology, mixed methods research has been conducted throughout the 20th century. From the late 1950s through the late 1970s, mixed methods research was in a formative stage. During this time, researchers were beginning to combine surveys and interviews as well as using qualitative and quantitative data results to support each other. Some researchers viewed this mixing of methods as a mixing of mutually exclusive paradigms. The issue of paradigm conflicts was and remains difficult for some researchers to overcome. Therefore, the 1980s and early 1990s were characterized by this paradigm debate. Purists, those who believed strongly in either qualitative or quantitative methods, did not believe it was appropriate to combine the paradigms. For example, quantitative researchers have contested the use of qualitative methods in scientifically based experimental research designs on the grounds that the designs have a methodological hierarchy in which quantitative methods are preferred and qualitative methods are consigned to a supplementary role.

Though this debate continues for many researchers, by the end of the 20th century, some researchers began to identify their methodology as a mix or blend of qualitative and quantitative research. From the mid-1990s to the present, these researchers have been attempting to further develop mixed methods research procedures. They have worked on definitions, notation, and a classification system for the different combinations of mixed methods research. The millennium brought about a call to make mixed methods research its own separate paradigm.

## Purpose

The main purpose for using mixed methods research is to balance the weakness of single methodologies. Both qualitative and quantitative research methodologies have weaknesses when used alone. One weakness in qualitative research is that small sample sizes are used. Consequently, qualitative researchers are unable to

statistically generalize the results to large groups of people. Mixing methods allows the researcher to study both small and large sample sizes in one study. Another perceived weakness of the qualitative approach is that researchers include their own interpretations and biases in the research.

Likewise, quantitative research has weaknesses. Usually the context of the study, the surroundings, and the environment are controlled and therefore not completely understood. Individual voices are not heard in a quantitative study. The researcher's biases are not usually explicitly addressed in quantitative research. Mixing qualitative and quantitative research results in a more comprehensive and therefore stronger study.

Besides strengthening the design and interpretation, mixed methods research allows researchers to answer questions otherwise unanswerable using only one approach. For example, a counselor may want to find out which coping skills are used and how widely those skills are used within certain ethnic groups dealing with the emotional aspects of diabetes. The counselor may use interviews or focus groups to identify emotional themes and coping skills used by each ethnic group. The researcher may then use a survey, developed from those themes, to determine the extent of use of those coping skills discovered using interviews. Without the first qualitative approach, the researcher may not be sure that the relevant emotional themes and coping skills used by each ethnic group had been identified. Without the second quantitative approach, the researcher may not be sure that the relevant emotional themes and coping skills identified in the smaller sample would hold true in a larger group of subjects from each ethnic group.

Though it is not a purpose of mixed methods research, one advantage of this method is that it promotes collaboration between qualitative and quantitative researchers. Because it is not common that a single researcher is adept in both types of research, experts in each methodology often form a research team. This collaboration encourages multiple worldviews. This paradigm is practical in that all types of data collection and analysis techniques are available to mixed methods researchers. It allows words and numbers to be combined to help understand complex systems.

## Procedures

There are four common types of designs in mixed methods research: *triangulation*, *embedded*, *explanatory*, and *exploratory*. Each has a different purpose.

### ***Triangulation Design***

In the triangulation design, the purpose is to use the strengths of both qualitative and quantitative research to support each other with the goal of comparing and contrasting the results of the qualitative and quantitative approaches in order to identify where the results agree or converge. When the results agree, this strengthens the validity of the study. The qualitative and quantitative portions of the triangulation design are usually done in the same time frame and are given equal weight. For example, a counselor may study the effects of suicide using both a quantitative standardized instrument and an in-depth interview. The results of both would then be merged into one overall conclusion.

### ***Embedded Design***

In an embedded design, the primary focus is on either the qualitative or the quantitative piece with the other type having a secondary role. A typical use of this design is in an experimental study that is primarily quantitative, in which one group is given a treatment and then compared to a control group or a group with no treatment. Quantitative methods such as the use of a standardized instrument are used to determine whether the treatment worked. However, a qualitative portion can be embedded in the design, which may include an in-depth interview of the participants before, during, or after the treatment. In this way the qualitative methods inform the overall quantitative study.

### ***Explanatory Design***

The explanatory design is a *sequential* design in which one type of research is followed by the other for purposes of further explaining what was found in the first portion. For example, a quantitative study may reveal that certain mental health clinics are outperforming others. A qualitative follow-up study would be conducted to try to understand, or explain, what those high-performing clinics were doing. The qualitative piece would involve interviews and a site visit to observe the effective practices.

### ***Exploratory Design***

The exploratory design is also a sequential design in which one type of research is followed by the other. However, the purpose in an exploratory design is to build on the results from the first type of research to a second phase of the research. A commonly used

exploratory design is to use qualitative methods to discover themes regarding an issue, and then use those themes to develop and administer an instrument that will generate data that will be analyzed quantitatively.

## **Data Analysis**

Data analysis depends on whether the design is concurrent or sequential. In a concurrent design, the qualitative data are organized and then analyzed separately from the quantitative data. Then the two results are combined for another round of data analysis. In a sequential design, a first methodology informs the second. Therefore, the analysis of the first portion is completed before beginning the analysis of the second portion.

### ***Data Analysis in Concurrent Design***

#### **Qualitative Data Analysis**

Qualitative data analysis begins with preparing the data, which means organizing the data, documents, field notes, or other visual data. Taped interviews are transcribed. Exploring the qualitative data is next and involves making notes about early observations as well as developing codes. *Codes* are words, phrases, or even sentences that are assigned to chunks of qualitative data that allow researchers to categorize the data into themes. Data analysis then involves the researcher coding the data by reading the raw data (field notes, interview transcripts, researcher observations, etc.) and assigning codes to small portions of the text. Codes are then grouped together to form themes. Themes can be grouped together to form more themes. Software packages are available to help develop themes in qualitative data.

The findings from the qualitative portion are then represented using rich descriptive narratives, discussions of the themes, and tables, figures, diagrams, or visual models. The qualitative data analysis is then combined with the quantitative data analysis for another round of analysis.

#### **Quantitative Data Analysis**

In the quantitative portion of data analysis in the concurrent design, the quantitative data also must be prepared for analysis. Numeric values are assigned to the data using a predetermined coding scheme. The data are entered into a computer software package. The data are “cleaned,” which means that the

researcher uses visual inspection and basic descriptive statistical procedures to identify and fix data entry errors. As in qualitative data analysis, exploring the quantitative data is next. This involves using descriptive statistics (e.g. measures of central tendency, measures of variation, and graphical representations) to check for patterns or trends in the data. The researcher chooses an appropriate statistical test to conduct the actual data analysis using inferential statistics.

Three types of inferential statistics techniques are commonly used; the choice of which will depend on the research question. The researcher may find and report a confidence interval, which is an estimate of a population parameter. The second type of inferential statistics commonly used is the hypothesis test. In hypothesis testing, a theory, belief, or hypothesis is tested using the data collected along with rules of probability. The third type of inferential statistics commonly used is regression. The goal in regression is to develop a mathematical model that describes the relationship between variables. For example, regression helps to describe what happens to one variable as another decreases or how much of the change in one variable can be attributed to the other variable changing.

### **Qualitative and Quantitative Analyses Combined**

In a concurrent mixed methods design, the qualitative and quantitative data analysis portions are completed separately and independently of one another. Once completed, the two data sets are merged. Three techniques for merging are typically used.

One technique is to transform one type of data into the other type. For example, qualitative data can be converted to quantitative data by counting the number of times certain codes or themes appear. Quantitative data can be converted to qualitative data by conducting a factor analysis, which is a statistical procedure that allows researchers to categorize quantitative data into themes; these themes can be considered qualitative.

A second technique for merging the two data sets is to use a *matrix*, which is a table in which the qualitative themes are arrayed along the top of the table and the quantitative results appear on the side of the table. The cells within the table are the conclusions about each category of results.

A third technique for merging the two data sets is to write a narrative discussion. The discussion could be used in conjunction with the matrix or stand alone.

In the discussion, the researcher compares and contrasts the results of both types of analysis and discusses how results converge.

### ***Data Analysis in Sequential Design***

Sequential designs are used with explanatory or exploratory designs and some embedded designs. The idea of sequential designs is that one type of data collection and analysis is used to inform the other type of data collection and analysis. If the qualitative portion is first in the design, then the data are collected and analyzed qualitatively first before starting the quantitative portion. The themes that emerge from the qualitative portion are commonly used to inform the quantitative portion in the form of the development of a quantitative instrument. If the quantitative portion is first in the design, then the data are collected and analyzed quantitatively first before starting the qualitative portion. An example of this type of study would be to use the quantitative results to help identify specific cases that can be investigated further using qualitative techniques, such as in the scenario above of following up on high-performing clinics.

### **Validity and Reliability**

Efforts to maximize the validity and reliability of research are standard practice in all paradigms. Validity assumes that what is being studied is in fact being studied. Reliability refers to the idea of repeatability or replicability. Would the study, if conducted again, yield similar results? Mixed methodology researchers need to maximize validity and reliability by using established methods to enhance validity and reliability in both qualitative and quantitative research. The exact methods used will vary depending on the research design. With the qualitative data, the methods may include triangulation, member or peer checks, and rich, detailed descriptions and salient quotes regarding the data. With the quantitative data, the researcher may discuss the previously established validity and reliability of the instruments used and identify threats to internal validity.

### **Future**

Mixed methodologists believe there are encouraging signs that this methodology is beginning to develop into a legitimate paradigm. For example, a journal has emerged recently that publishes only studies that use

mixed methodology designs. Also, basic research textbooks are starting to include sections on mixed methodology. Mixed methodologists believe that this third paradigm will increase the ability of researchers to draw from the strengths of quantitative and qualitative methodologies without having to sacrifice the strengths of one methodology for the weaknesses of the other. The future of mixed methodology will be fueled by the advantages discovered through the more comprehensive picture created by combining qualitative and quantitative techniques.

without it. Music is a part of many social activities and is present in much of our environment. People may use music to communicate with others and often respond emotionally to music. Music has been a part of all cultures, and people report listening to music more than any other activity over a wide variety of contexts.

Music affects people emotionally, physically, and aesthetically, and these responses provide the basis for the use of music in therapy. Emotional responses may include nostalgia at hearing a song, sadness evoked by a piece of music, or joy and exhilaration while dancing to music. Music influences physiological responses such as changes in heart rate, electrical skin conductance, and breathing, and it also affects physical and brain responses. Aesthetic responses reflect one's experience of the beauty and art of music.

Music and healing have been tied together throughout history. Shamans have used music in healing since primitive times. The Greek philosophers Plato and Aristotle wrote of how to use music to affect health and behavior, and music continued to be tied to healing throughout the Middle Ages and later. Music has been used to treat physical and mental problems in the United States for the last century and a half.

Formal music therapy in the United States stems from the period during World War II, when musicians played their instruments for veterans with physical and emotional trauma in Veterans Health Administration hospitals. Their music often had a positive effect on the hospitalized veterans, and the medical personnel began to request that hospitals hire the musicians. It became clear that the hospital musicians needed some training before working in the facilities, and the demand grew for a college curriculum. The first music therapy degree program in the world began in 1944, followed by the first music therapy association in 1950. The American Music Therapy Association (AMTA), the current U.S. association, was founded in 1998 through the unification of older music therapy organizations.

AMTA establishes standards and oversees music therapy education and training in the United States. Music therapy training is offered at the bachelor's level or higher at over 70 educational institutions approved to offer music therapy degrees. Bachelor's level training leads to entry level competencies in musical, clinical, and music therapy foundations and principles; these are acquired through academic coursework and 1200 hours of clinical training that includes a supervised internship. Many universities offer master's and doctoral degrees in music therapy.

---

## MUSIC THERAPY

---

Music is such an important part of life that some find it difficult to imagine what the world would be like

Music therapists also may obtain graduate degrees in music therapy or a related field such as special education, social work, or gerontology. The Certification Board for Music Therapists (CBMT) establishes competencies for music therapists to become Board Certified Music Therapists (MT-BC), the credential necessary to practice music therapy, and requires continuing education to ensure that music therapists' skills are up to date.

Music therapy is well established in many parts of the world, and many countries in addition to the United States have standards for educating and training music therapists, governmental regulations for music therapy, and active music therapy associations. The World Federation for Music Therapy (WFMT) is dedicated to the promotion and development of music therapy worldwide. *Voices: A World Forum for Music Therapy* is a regular online publication that presents information and opinions on music therapy from around the world. *Music Therapy World* publishes articles, online databases, and additional information about music therapy. These Web sites provide international networking opportunities for music therapists and others interested in music therapy and increase international awareness and communication.

### Definition and Scope

Music therapy is defined by AMTA as "the clinical and evidence-based use of music interventions to accomplish individualized goals within a therapeutic relationship by a credentialed professional who has completed an approved music therapy program." Music therapists use the unique qualities of music and a relationship with a therapist to access emotions and memories, structure behavior, and provide social experiences in order to address clinical goals.

Music therapy may be used with children or adults with physical or emotional problems or with healthy people to achieve higher levels of awareness. Music therapists work with clients with a range of diagnoses. The client groups listed below, arranged from more to less frequently served, are those served most frequently by music therapists as reported by AMTA in 2006, but they are only some of the many client groups that music therapists see. They include clients who are developmentally disabled, those with autism spectrum, the school-age population, clients with behavioral disorder, clients with mental health issues, multiply disabled individuals, elderly persons, physically disabled

individuals, clients with Alzheimer's disease or some other form of dementia, speech impaired clients, emotionally disturbed clients, learning disabled clients, clients in early childhood, neurologically impaired clients, visually impaired clients, individuals with dual diagnoses, stroke victims, and hearing impaired clients.

Music therapy methods may be both active and receptive. Active methods involve the client *doing* something with the music; with receptive methods, the client is *receiving* the music, generally through some form of listening. All may include verbal processing of feelings and experiences, particularly with adults.

Bruscia divides uses of music in therapy into four methods: improvising, performing or re-creating, composing, and listening experiences. Improvising occurs when the client makes up music using any medium, individually or with others. Performing or re-creating takes place when the client learns or performs precomposed music. Composing experiences involve the client writing songs, lyrics, or instrumental pieces with the assistance of the therapist. In listening experiences, the client listens to music of any type and responds silently, verbally, or in another modality.

Music therapy as psychotherapy may occur at three levels. In *supportive, activity-oriented* music therapy, goals are achieved through the use of therapeutic activities (including verbalization when appropriate), but understanding why a behavior occurs is not important. In *re-educative, insight- and process-oriented* music therapy, the focus is on feelings, the exposition and discussion of which lead to insight that results in improved functioning. Music may be used to elicit emotional or cognitive reactions necessary for the therapy. In *reconstructive, analytically, and catharsis-oriented* music therapy, the music helps to elicit unconscious material, which is then worked with in an effort to promote reorganization of the personality. Music therapists may work at one or more of these levels depending upon the needs of the client and the skills of the therapist, with more advanced training required at each level.

### Clinical Examples of Music Therapy

Music therapy can be used in numerous ways, as suggested by the methods and levels described above. Client needs, abilities, and interests are primary considerations in determining music therapy techniques.

A few examples of music therapy, selected to illustrate a variety of clients and approaches, are given below.

### ***Children With Developmental Disabilities***

Music therapy is effective for treating a wide range of problems of children with developmental disabilities and with multiple disabilities. Lisa began music therapy when she was 9 years old and received individual music therapy that was written into her individualized education program (IEP). She had multiple severe disabilities and was nonverbal, although she occasionally made some sounds. Goals for her music therapy were to increase eye focus to task, improve responses to commands, increase frequency of vocalizations, and improve bilateral use of her hands. Music therapy techniques included encouraging Lisa to play simple rhythm instruments, sometimes in response to directions from the therapist; playing songs that encouraged her to respond vocally; and having her do structured movement to music, often to directions given in the song and encouraged by the therapist. She improved in all areas, including some instances in which she said words that were distinguishable. After 2 years (82 sessions), Lisa began music therapy with the same music therapist in her school so that she could work on social skills with her peers. Sessions were held for the next 2 years in the school, with goals including increasing use of her voice, cooperating with others and increasing interpersonal relatedness, following simple directions, and increasing two-handed use of objects. Lisa continued to make progress toward many of the goals, although her responses were inconsistent.

### ***Medical Settings***

Music therapy is effective in medical settings with adults and children. Barbara L. Wheeler has worked in several medical settings, and her work with one young man will serve as an example.

Steven was 19 and hospitalized for a brain tumor. Optic glioma, diagnosed when he was 5, had now progressed so that he could not see and was confined to his hospital bed on the intensive care unit. He had other problems, including muscular dystrophy and hydrocephalus. Because he was hospitalized for an extended period of time, Steven had eight music therapy sessions. Goals were to decrease isolation, provide an opportunity for emotional expression, and increase stimulation. The music therapist usually sang

songs of Steven's choice and encouraged him to tap on a tambourine as a way of participating. He found the sessions useful and usually expressed his enjoyment by smiling, playing the instrument, and speaking of his pleasure. On one occasion, a familiar melody ("You Are My Sunshine") provided the outline for a song about what he had done that day. He was responsible for choosing the words to insert in the blanks when words were left out of the song. The song went, "Today I lay in bed, and I had pancakes. My mom was here and she loves me." Steven was gratified by this creative endeavor, and his mother cried with emotion at Steven's creation. Steven was transferred to a long-term facility and passed away within a few months.

### ***Adults With Psychiatric Disorders***

Working with people with psychiatric disorders, or in the mental health area, is a common focus of music therapists' work, and music therapy has been found to be successful with this population. Additional evidence of the usefulness of music to address the problems of adults with psychiatric disorders is provided by research on aspects of music therapy used with these problems, including those related to depression. Two types of in-depth work are described.

Diane Austin uses vocal improvisation in analytically oriented music therapy. Vocal psychotherapy uses the voice, vocal improvisation, song, and dialogue to promote intrapsychic and interpersonal change within a client-therapist relationship. Austin uses the voice because she finds that singing connects people to their breath, their bodies, and their emotional lives. She uses techniques such as "vocal holding," involving the client and therapist singing together over two consistent chords in unison; harmony; and mirroring to provide a reparative experience and work through developmental arrests.

The Bonny method of guided imagery and music (BMGIM) is an important way of using music as therapy. This method, developed by Helen Bonny beginning in the 1970s and described by Bonny in 2002, is usually done in an individual session with a trained therapist serving as the guide. The client, in an internally focused state, listens to specially programmed classical music that may evoke emotions, memories, imagery, moments of healing and transformation, and spiritual experiences. The client's imagery comes from the client's experience of the music and is not directed by the therapist. The development and theory

of BMGIM, plus numerous instances of deep and transformational experiences with this method, are documented in the literature.

## NORCROSS, JOHN C. (1957– )

---

John C. Norcross is a professor of psychology and distinguished university fellow at the University of Scranton and an internationally recognized authority on behavior change and psychotherapy. Norcross received his B.A. degree in psychology at Rutgers University (1980) *magna cum laude*, and his M.A. (1981) and Ph.D. (1984) degrees in clinical psychology from the University of Rhode Island. Norcross is a licensed psychologist in the Commonwealth of Pennsylvania and is board certified by the American Board of Professional Psychology in clinical psychology. He and his wife, Nancy, have two children, Jonathon and Rebecca.

Expertise in a field can result in a singular focus on a circumscribed topic in one or two publications. Norcross has opted for the opposite: a wide focus on several topics of critical import to counselors and psychotherapists. As an educator and trainer, Norcross is among those in the psychology profession who have published across the spectrum and in many very prestigious publications. His extensive contributions to psychological science, training, and practice are in areas such as psychotherapy integration, therapeutic relationships, evidence-based practices, psychotherapist self-care, and practice resources. Norcross has cowritten or edited 15 books, authored 50 book chapters and 250 journal articles, and delivered over 350 professional presentations and workshops in these areas of expertise in 24 countries. The impact of his contribution is found not only in the number of publications but also in their breadth and practicality. He has published in many different domains of psychology, including

teaching journals; clinical, school, and counseling journals; integration and eclectic journals; common factors and alliance research journals; and key publications based in social work, education, and psychiatry.

Recognition for his work has included the 1992 Krasner Early Career Award from the American Psychological Association (APA) Division of Psychotherapy, the 1992 Pennsylvania Professor of the Year from the Carnegie Foundation, the bestowing of fellow status from the American Psychological Association in 1996, the 2003 Rosalee G. Weiss Award from the American Psychological Foundation, the 2004 Distinguished Psychologist Award from the APA Division of Psychotherapy, and most recently the APA 2005 Distinguished Contributions to Education and Training Award.

In addition to the honors and awards, Norcross has served in prestigious leadership positions in the profession. He is council representative of the APA Division of Psychotherapy, member of the APA Policy and Planning Committee, and a member of the Board of Directors of the National Register of Health Services Providers in Psychology. He is past president of the International Society of Clinical Psychology and the APA Division of Psychotherapy and was a member of the APA Presidential Task Force on Evidence-Based Practices in Psychology.

### **Contributions to Education and Training**

Norcross's influence on clinical training traverses all levels of higher education, from the undergraduate level through professional development to continuing

education. At the undergraduate level, his coauthored *Insider's Guide to Graduate Studies in Clinical and Counseling Psychology* is revised every two years and more than 75,000 copies have been sold to potential graduate students. At the graduate level, the Prochaska and Norcross *Systems of Psychotherapy* is now in its sixth edition and its third decade of educating students. It was one of the earliest texts to advocate comparative analysis and an integrative, evidence-based perspective. His recent *Psychotherapy Relationships That Work*, similarly, introduces evidence-based training in customizing the therapeutic relationship to the individual client.

At the professional level, Norcross and his colleagues have promoted training through publications on self-help and self-change and on psychotherapy integration, and he has also produced numerous psychotherapy videotapes. Practical teaching tools for all three include the *Authoritative Guide to Self-Help Resources in Mental Health*, which describes the most effective self-help books, films, autobiographies, and Internet sites based on eight national studies involving over 3,500 clinical and counseling psychologists. With several colleagues, Norcross coordinated 12 videotapes on systems of psychotherapy (Series I) and 12 additional videotapes on psychotherapies for specific problems and populations.

### Contributions to Research and Theory

Early in his career, Norcross began writing on the common factors, psychotherapy integration, and treatment-relationship matching. His influence on theory development is evidenced through the aforementioned text, *Systems of Psychotherapy: A Translational Analysis*, which highlights the stages of change and change processes. He has advanced research on the theoretical concepts developed in his models. These studies focus on therapeutic commonalities, exploring paths toward integration, obstacles to psychotherapy integration, supervision of integrative psychotherapy, prescriptive matching, and delineation of empirically based principles in psychotherapy. His coedited text, *Handbook of Psychotherapy Integration*, continues to have an impact on how trainers, researchers, and practitioners think about the evolution of psychotherapy.

From 1999 through 2002, Norcross chaired the APA Division 29 Task Force on Empirically Supported Therapy Relationships. From the work of this task force came his edited text *Psychotherapy Relationships*

*That Work*, which he considers “the most exciting of my career and potentially the most significant.” The book represents the first time that the research evidence on clinical attempts to individualize the therapy relationship has been aggregated in a single source. Because of his expertise in elements of the therapeutic relationship, Norcross was appointed in 2005 to the APA Presidential Task Force on Evidence-Based Practices in Psychology. The document produced by the task force has set the course for defining the profession’s response to the juggernaut of evidence-based practice in mental health. Subsequently, in 2006, he coedited *Evidence-Based Practices in Mental Health: Debate and Dialogue on the Fundamental Questions*, a book that highlights critical points of convergence and remaining points of contention.

Norcross serves the profession through his editorial appointments to over 15 journals. He is the editor of the *Journal of Clinical Psychology: In Session* and currently serves on the editorial boards of the *American Journal of Psychotherapy*, *Professional Psychology*, *Psychotherapy*, *Clinical Psychology & Psychotherapy*, *Pragmatic Case Studies in Psychotherapy*, the *Oxford University Press Textbooks in Clinical Psychology*, and the *Journal of Clinical Psychology*. He has served as the editor of the Brunner/Mazel Integrative Psychotherapy book series and as associate editor of the *Journal of Psychotherapy Integration* for 10 years.

His ongoing research into graduate education and graduate admissions has advanced the field through publication of many articles on such subjects as evaluating clinical training, evaluation activity in training clinics, training integrative psychotherapists, and evaluation of internship training.

### Contributions to Practice

Norcross is roundly recognized by practitioners for his application of clinical experience and research evidence to the practice of psychology. He is viewed by clinicians as an educator and training professional whose writings bring a scientific framework to the practice of psychology. He has written eloquently and effectively for the practice audience in several areas. Some of these publications include texts such as *The Psychologists' Desk Reference*, *Casebook of Eclectic Psychotherapy*, *Handbook of Psychotherapy Integration*, and *The Authoritative Guide to Self-Help Resources*.

It is evident in his publications and his presentations that Norcross values both research and practice

and is among those who find commonalities rather than differences. He has delivered many workshops and presentations on the continuing convergence and contention between these domains and has written most effectively on the subject.

The development of the psychotherapist as a person is an important focus of both writing and training for Norcross. He has devoted two coedited books to this subject—*The Psychotherapist's Own Psychotherapy* and *Leaving it at the Office: Psychotherapist Self-Care*—as well as numerous articles and chapters that chronicle his observations and expertise in the area. In addition, Norcross has published many articles that identify the importance of professional development in terms of self and one's larger identity with the profession. His publications exemplify this concern: Consider, for example, his research on clinicians' theoretical orientations, national surveys of mental health professionals, dimensions of psychotherapeutic skills and techniques, self-change in psychological distress, values in psychotherapy, and conducting psychotherapy with psychotherapists.

In concert with his students, Norcross has conducted multiple national surveys that chronicle the evolution of the profession over the past 25 years. Further, he has conducted presentations and workshops in advancing the discussion of the future of psychology and psychotherapy. Among these contributions are Delphi polls on the future of psychotherapy every 10 years, roundtables on psychotherapy breakthroughs, and lifelong lessons on and studies of the great books of psychology.

---

## OCCUPATIONAL STRESS

---

Occupational stress is a broad concept that has been defined in a variety of ways in the popular and professional literature. It is generally agreed that occupational stress consists of the harmful physical and psychological consequences to individuals that result when an imbalance exists between demands of the work environment and individual needs, abilities, and resources. Most people experience some level of occupational stress on occasion, and it is generally believed that such short-lived, episodic experiences do not pose serious or lasting harm to the individual. However, when a significant level of occupational stress persists for an extended period of time, potentially serious physical and psychological harm may occur. Although occupational stress is most often considered to be undesirable, the notion of *good stress*, also referred to as *eustress*, has been used to describe stress that motivates and energizes the worker to learn new skills and perform more effectively, without the debilitating impact typically associated with occupational stress. In the case of good stress, the result of having successfully mastered the challenge posed by the stressful condition is a sense of personal satisfaction and achievement.

Occupational stress in the American workplace is widespread and appears to be growing. When asked about primary sources of stress in their lives, a substantial number of people point to conditions in their work environments such as long hours, workload, poor communication, management problems, and lack of support, to name several examples. Recent surveys of workers suggest that as many as 80% of workers

experience stress in their work, and 40% of respondents find their work to be *very* or *extremely* stressful. Occupational stress poses a very real threat to the quality of life for employees within an organization as well as a serious threat to the productivity and profitability of the organization itself.

### Individual and Organizational Perspectives

Efforts to explore the origin of occupational stress have approached the question from the perspectives of both the individual and the workplace environment. Obviously, characteristics of the individual and the work environment interact to produce the various individual and organizational outcomes observed in studies of occupational stress.

#### *Individual Perspective*

When individuals experience stress, the brain mobilizes the body's systems for defensive action in what is commonly known as the fight-or-flight response. This response is characterized by an increase in various bodily hormones that stimulate an increase in several vital functions such as heart rate, respiration, blood pressure, and muscle tension. This fight-or-flight response plays a key role in humans' ability to protect themselves when in potentially dangerous situations, either by fleeing or fighting. However, if the stressful situation persists unresolved, the prolonged arousal of vital functions may eventually deplete the body's resources, contributing to injury or disease.

### Symptoms

According to the National Institute for Occupational Safety and Health (NIOSH), a federal agency responsible for research and policy on matters of work-related illness and injury, several symptoms have been identified as early warning signs of occupational stress. These symptoms may include headaches, difficulty concentrating, sleep disturbances, upset stomach, mood disturbances, job dissatisfaction, and disturbed relationships. These early warning signs are fairly easy to recognize. Of greater concern, however, is the fact that prolonged occupational stress can contribute, in concert with other factors, to more serious physical and mental health problems that are chronic in nature and potentially life threatening. NIOSH has identified three broad categories of health problems believed to be associated with prolonged stress that include cardiovascular disease (e.g., heart disease, high blood pressure), musculoskeletal disorders (e.g., tendonitis, lower back pain), and psychological disorders (e.g., anxiety, depression).

In addition to physical and psychological difficulties, it has also been shown that individuals experience stress as a result of competing work and family roles, that is, work–family conflict. With the increase in the number of women in the workforce, the growing number of dual-worker families, and the changing nature of men's and women's roles in American society, it is not surprising that a significant number of people report difficulties managing the often competing demands associated with their work and family roles. Many employees with families report feeling torn between expectations of them in the workplace and their responsibilities as spouses and parents. This conflict can further contribute to the level of stress experienced.

### Influencing Factors

It has been well established that individual characteristics have a significant impact on an individual's perception, experience, and management of stress. Two individuals employed in the same work setting may provide very different reports of their own occupational stress as a result of their unique perspectives, preferences, needs, values, abilities, and experience. Perspectives may be so divergent that one person experiences stress as a positive phenomenon, serving to arouse and motivate strong performance or signify the need for a change in work or lifestyle. Another person may experience stress as negative and

disruptive of performance. Often, both perspectives prove true; that is, stress may be viewed as positive and functional in the short term, but, over time, prolonged stress becomes deleterious to the individual as it weakens, erodes, and undermines psychological and physical health.

The nature and extent of occupational stress experienced, as well as one's response to it, appears to be influenced by several different personality characteristics. Not surprisingly, individuals who are highly idealistic, set unrealistic goals, overidentify with others, and have a high need for self-affirmation tend to demonstrate greater vulnerability to occupational stress. Individuals who have an *internal locus of control* (tend to attribute outcomes to their own efforts rather than to factors outside of their control such as luck or chance) tend to be somewhat less susceptible to occupational stress than those with an *external locus of control*. Self-efficacy, the belief that one has the ability to respond effectively to the demands of the work situation, appears to buffer against the negative impact of stress. Finally, an active coping style, or one in which the individual faces challenges directly and proactively, has been associated with lower levels of occupational stress as well as with more effective response strategies for managing existing stress.

### Intervention

When the focus of occupational stress is the individual, the emphasis of intervention is on helping the individual to manage the stress being experienced in a way that minimizes or eliminates the negative impact of stress on work performance and the individual's health. Many companies provide stress management assistance to their employees as a benefit of employment. This assistance might include psychoeducational programs designed to teach workers about occupational stress and its potential effects on life and health as well as strategies for reducing work-related stress. Such strategies might also include training in specific behavioral management techniques such as time management and relaxation, for example. Employee assistance programs (EAPs) are another form of help that is frequently provided on-site by employing organizations. EAPs are typically staffed by professionals with training in mental health service delivery and offer individual counseling for both work-related and personal problems. According to NIOSH, although interventions focused on stress

management are often relatively inexpensive and effective in reducing symptoms of occupational stress, the benefits are often short-lived. Furthermore, because the problem of occupational stress is so widespread, interventions that target employees more broadly have the potential for greater impact. Finally, interventions focusing on the individual often ignore or overlook the real sources of the problem that exist in the work environment. For these reasons, interventions that are targeted at the work environment are often preferable.

### ***Organizational Perspective***

Organizations are complex systems structured to accomplish specific tasks (e.g., manufacture a product, provide a service) and to provide control and accountability. Although modern theories regarding organizations tend to discourage rigid, hierarchical, bureaucratic designs, these characteristics are true of most current organizations, at least to some degree. Many of these features of organizations, as well as the environments within which they operate, are sources of stress for employees who work in them. The symptoms of occupational stress may be found in the behavior of employees or in patterns within the organization's structure.

### **Symptoms**

Many different symptoms point to stress in the work environment. High levels of job dissatisfaction and related concerns are almost certain to arise eventually in stressful environments. Chronic absenteeism and tardiness are often common in highly stressful work environments, too. An unusually high turnover rate among employees is another common symptom of occupational stress that can be quite costly to the organization in terms of the time and resources required to train new people. Negative social behaviors, such as aggression, may occur more frequently in highly stressful environments. The term *going postal*, coined after several incidents in which disgruntled postal employees shot and killed fellow workers, has come into popular use to refer to workplace anger and violence. Increasing frequencies of stress-related physical and psychological problems among employees contribute to substantial increases in health-care costs. Declines in productivity and the quality of workmanship are also common manifestations of a

highly stressful work environment. Left unresolved, these symptoms can have devastating effects on the organization and the people employed there.

### **Influencing Factors**

It is generally agreed that work environments have become increasingly more stressful over time. Downsizing (cutting positions or services to save costs), outsourcing (delegating jobs or services to external specialists to cut costs), and the growth of non-permanent employment contracts are examples of changes that have contributed substantially to making employees' work lives more stressful. Many workers believe their jobs are less secure than before and feel as though they have less control over their work lives. One of the most prominent theories of job stress hypothesizes that job demands interact with control to influence the amount of stress likely to be experienced. For example, high job demands are likely to be experienced as more stressful when employees have less control over their work than when they have more control.

Organizations are often described as complex human systems, composed of several important subsystems that are highly interdependent. These subsystems, although referred to by various names, exist within all organizations and compose the organization's structure. Three commonly identified subsystems include the operational (includes communication, roles, authority, power, norms, reward systems), purposive (includes goals, objectives, mission, core values), and methodological (includes technology, procedures, materials used) subsystems. Not surprisingly, different types and sizes of organizations operate most effectively with different types of structures. When given elements of an organization's structure are poorly designed or managed, the result can be considerable workplace stress. For example, expectations for employees with specialized skills to serve in multiple roles may result in excessively heavy workloads and long hours for those individuals. Likewise, excessive noise or overcrowding in the workplace may occur as a result of specific technology or procedures being used. Both of these examples illustrate how structural elements of the organization can produce stressful conditions for workers. If such conditions are permitted to persist over time, it is likely that symptoms of stress will eventually emerge both in the work environment (e.g., through reduced productivity) and in the physical and psychological health of employees.

Leadership style is a very important element of organizational structure that can greatly impact workplace stress. Leaders can influence the nature and quality of the work environment in several important ways. For example, leaders can either encourage or discourage open communication across individuals and groups within the organization. Rigid, bureaucratic leaders typically tend to discourage employees from communicating effectively with one another (horizontally) and with the leaders themselves (vertically). Poor communication may inhibit the quantity and quality of information that is available and considered in decision making within the organization. Potentially negative outcomes from poorly informed decisions may further contribute to workplace stress.

### Intervention

Given the magnitude and breadth of the problem of occupational stress, it is generally believed that interventions that focus on changing the structure of the organization (work environment) will produce more effective and more enduring outcomes than interventions focusing on individual employees. In light of the fact that so much of work-related stress can be attributed to problems in organizational structure, it makes good sense to design organizations in ways that facilitate strong work performance while minimizing the stress experienced by employees of the organization. In the past, it was largely assumed that stress was an inevitable companion to organizational productivity. However, considerable evidence has emerged to suggest that the opposite is true; that is, productivity and worker satisfaction will be higher in organizational environments that optimize the health and welfare of employees.

Remedial approaches that focus on treating individual casualties of the stress produced in work environments will always be necessary and appropriate. Thus, there will be a continuing place for procedures designed to foster more effective management of stress at the individual level. However, the most desirable approach is one that is preventive in nature. Such an approach will require creating and maintaining work environments that are highly sensitive and responsive to the needs of workers. In reality, the most successful efforts to addressing workplace stress will likely incorporate both individual and organizational interventions.

There are many different models for facilitating organizational change, but they tend to share several

common elements. For example, those to be affected by future change(s) ought to be included in all aspects of the change process. This kind of inclusion fosters ownership of the change, increases the likelihood that the change will meet the needs of those affected by it, and reduces the likelihood of resistance due to perceptions that change is being imposed. Collaboration among affected parties in identifying problems and designing and implementing changes will increase the likelihood that plans are based upon sound information and diverse perspectives. The feelings and preferences of individuals must be considered along with factual data. Finally, the worth and dignity of the individual is of paramount importance.

## OPPOSITIONAL DEFIANT DISORDER

---

Oppositional defiant disorder (ODD) is a condition prevalent in a significant percentage of children that adversely impacts the individual and also affects the family, school, community, and society. Early awareness of and intervention in ODD is crucial in stopping a potentially dangerous and destructive progression to a more serious disorder. However, as oppositional behavior is a normal part of development for young children and early adolescents, clinicians need to exercise caution when assessing and diagnosing ODD in order to avoid misdiagnosis.

### Definition

The American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV)* defines ODD as a childhood disorder characterized by an ongoing and persistent pattern of hostile, noncompliant, and resistant behaviors manifested toward authority figures. In order to attain a diagnosis of ODD, behaviors must consistently occur for at least 6 months. Individuals with ODD are often described as stubborn, easily angered, argumentative, verbally aggressive, quickly annoyed by others, externally blameful for personal mistakes, deliberately annoying, and physically aggressive. In addition, such children easily lose their temper on a consistent basis and may demonstrate vindictive behavior. Often, children with ODD possess a low frustration tolerance and have difficulty controlling impulses. Last, individuals with ODD typically procrastinate and dawdle when expected to comply with a command. They commonly lack insight into their behavior and view their noncompliant behavior as an acceptable response to overdemanding situations.

ODD can cause significant difficulties in many areas of a child's life, including the family and school environment. Typically children with ODD have a difficult time getting along with family members (i.e., siblings, parents) and may find it hard to initiate or maintain peer relationships. Although children with ODD often have difficulty forming positive relationships with individuals of authority (i.e., teachers, coaches), defiant behaviors are sometimes solely present with individuals with whom the child has a close relationship.

### Prevalence and Onset of Symptoms

Although studies differ in reported statistics, an estimate of the prevalence rate for ODD ranges from 2% to 16%. In addition, the *DSM-IV* states that ODD tends to be more common in males prior to puberty, but prevalence rates even out between males and females following puberty. ODD is typically noticeable before the age of 8 and is not commonly evident soon after adolescence commences. Onset of symptoms is not sudden, and behaviors tend to slowly manifest over the course of several months or years. As younger children develop more sophisticated verbal capabilities, defiance may advance from simple refusals to more sophisticated oppositionality (i.e., negotiations).

### Associated Difficulties

Problems commonly associated with ODD include low self-esteem, substance use or abuse, and frequent mood fluctuations. In addition, ODD may be an early indicator of a more severe psychopathology but does not necessarily precede a more severe condition. In some cases, ODD may progress into conduct disorder (CD), a disorder characterized by socially inappropriate (i.e., law breaking) and destructive behaviors. Children with ODD were 4 times more likely to develop CD than were children without ODD, although the risk of development from ODD to CD in females is somewhat unclear. Longitudinal research conducted by Hinshaw, Lahey, and Hart has shown that half of children with ODD progress to CD, 25% maintain the ODD diagnosis, and 25% eventually discontinue showing clinically significant levels of externalizing behavior. Last, attention deficit hyperactivity disorder (AD/HD), learning disabilities, and mood disorders commonly coexist with ODD, and interventions targeting these conditions may reduce oppositional behavior.

### Assessment

In order to obtain a comprehensive assessment of ODD, a clinician should adopt a multifaceted approach in which a variety of domains are explored. In addition, the assessment should employ a number of ways to gather information from multiple individuals in the child's life.

Often when assessing for ODD, clinicians engage in a structured diagnostic or clinical interview with

both the child and the parent(s). A structured interview is a diagnostic assessment with pre-established questions that can be scored in an objective fashion. A clinical interview is important in order to assess the frequency of behaviors, level of impairment for the child and family, and antecedents (e.g., a request from a parent or teacher) and consequences (e.g., time-out) that surround the oppositional behavior. In addition, both structured and clinical interviews are helpful in determining the presence of other psychiatric conditions. Last, interviews with the child are helpful aids to parent interviews.

In addition to interviewing the child and other authority figures in the child's life, clinicians also administer self-report behavioral rating scales, such as the Child Behavior Checklist (CBCL), to the child, parents, and teachers. These assessments are useful in gathering a broad range of information as well as information about specific behaviors. Also, like the interview, some rating scales provide data that may be helpful to guide diagnostic decisions.

Last, in order to corroborate information gathered in both the interview and the self-report measures, behavioral observations are often conducted. McMahon and Wells point out that behavioral observation is crucial in the assessment process in that it allows a clinician to observe parent-child or teacher-child interaction patterns and to assess change in the communication patterns as treatment progresses.

## Treatment

### *Psychosocial Intervention*

Treatments for ODD are eclectic and may include individual therapy, family therapy, and behavioral modification plans. Although psychodynamic and humanistic approaches to treatment are available, treatment typically focuses on cognitive-behavioral approaches, as they have received the most empirical support. Behavioral parent training programs are based on social learning principles that suggest children learn noncompliance through a process of modeling and reinforcement for externalizing behaviors from individuals in their environment, particularly parents. Therefore, parents are taught to recognize and change their parenting behaviors in order to enhance their child's prosocial behaviors and decrease inappropriate behaviors.

Behavioral parent training programs also focus on relationship building and teaching effective discipline techniques. In the relationship component, parents are

taught skills to enhance communication patterns and to foster a stronger parent-child bond. During this component, parents are taught to follow the child's lead during a play situation, to recognize and praise positive behaviors, and to systematically ignore minor inappropriate behaviors (e.g., differential attention). The discipline portion of behavioral parent training focuses on teaching parents how to give effective commands, to consistently praise compliant behavior, and to effectively implement a time-out contingent upon noncompliant behavior. Behavioral parent training programs employ a variety of methods to teach behavior modification techniques, including didactic instruction, role-play, modeling, live coaching, and practicing in both the clinic and home environment.

### *Psychopharmacological Intervention*

Although some pharmacological interventions have shown promise in reducing oppositional defiant behavior, the literature continues to assert that psychosocial treatment is the gold standard in treating this disorder. Few randomized clinical trials have investigated the effects of medication on ODD in isolation. However, Newcorn, Spencer, Biederman, Milton, and Michelson examined the effect of psychopharmacological agents on ODD when the disorder is an adjunct to AD/HD and have found positive results. Although research suggests that certain psychopharmacological agents may be a well-tolerated and effective treatment for ODD, further investigation is warranted in this area.

## Clinical Considerations

### *Assessing Age-Appropriate Behavior*

One factor that needs to be considered in making a diagnosis of ODD is whether the frequency and intensity of behavior problems occur outside of the expected range for a child's mental age and developmental level. An individual with ODD tends to show a recurrent pattern of negativistic behavior as opposed to episodes of transient temper tantrums and disobedience that do not greatly impair daily functioning. It is developmentally appropriate for young children to occasionally act out and refuse to obey commands. For example, normally developing 2- or 3-year-old children typically begin to seek more autonomy from their parents, and with this independence come more occasions for parent-child disagreements. In addition,

beginning school can be a difficult endeavor for any young child and may set the stage for mild disagreements with peers. Typically, peer-related arguments and disagreements quickly diminish as children learn more positive ways to interact. For this reason, a clinician must separate behavior that is developmentally appropriate from that which occurs more frequently and with more severity.

### **Differential Diagnosis**

As externalizing behaviors exist on a spectrum, it is important to differentiate ODD from other behavior disorders such as conduct disorder. The chief factor separating ODD from CD is that children with ODD do not engage in behaviors that violate the basic rights of others or break age-appropriate societal norms. Children with ODD tend to manifest overt, nondestructive behaviors that are typically easy to detect. On the other hand, children with CD typically demonstrate more destructive, aggressive behaviors (overt and covert) that may endanger the safety of themselves or others. For example, an individual with CD may cause harm to animals, set fires, vandalize, or run away from home for long periods of time. It is worth noting that most individuals with CD meet diagnostic criteria for ODD, but a diagnosis of CD is made when both diagnoses can be given.

### **Case Example**

Daniel, age 5, was referred to the clinic due to his oppositional and verbally aggressive behaviors at home and at school. At home, Daniel often refused to listen to his parents and would lash out at his little sister. On more than one occasion, Daniel's parents felt unsafe around him during his meltdowns. Daniel's parents stated that they felt like they were constantly walking on eggshells at home, and even the smallest incident would set him off. They described Daniel as a "difficult" baby and said they felt like he had never progressed beyond 2 years of age. Daniel often would scream, "I hate you" to his parents when they asked him to do even the simplest task. In addition, Daniel constantly blamed his little sister for incidents that he was clearly responsible for.

At school, Daniel was constantly getting in trouble for his behavior. He frequently yelled at his teacher and rarely listened to instructions. On occasion, Daniel would run out of the classroom without permission and disrupt other children in the hallway. Daniel's teachers said that he was constantly teasing other children for

"no reason whatsoever" and often held grudges against other children. For his bad behavior, Daniel consistently received "red lights" from his teacher and missed recess at least 3 times a week. Daniel had seldom been physically aggressive with others and did not engage in more dangerous behaviors such as fire-setting, maliciously lying, or displaying developmentally inappropriate sexual behavior.

Daniel's parents stated that they had "tried everything," and nothing seemed to work with Daniel. They reported that he was constantly in time-out but that it did little to diminish his bad behavior. Also, they said that they took everything away from Daniel when he acted out until they had no privileges left to take away. Daniel's parents were concerned that his quick temper and lack of flexibility would lead to a larger problem in the future and negatively affect his relationships with them, his sister, and his peers.

In order to reduce Daniel's oppositional behavior and improve the quality of life at both home and school, the therapist recommended behavioral parent training and had Daniel's parents commit to six sessions. During treatment, Daniel's parents learned ways to effectively communicate with Daniel. For example, Daniel's parents learned the importance of social reinforcement and that praising Daniel for a specific behavior would increase the likelihood of that behavior occurring again. Also, Daniel's parents learned how to remove their attention for negative behaviors. Last, his parents learned effective ways to give instructions to Daniel and to administer appropriate consequences to Daniel's responses. After eight sessions, Daniel's oppositional behavior diminished at both home and school, and he not only began to receive fewer "red lights" but also began to bring home "green lights" for good behavior.

## PARENT–ADOLESCENT RELATIONS

---

Parents and their children relate, or interact, on a number of different levels: as playmates, as teacher and student, as healer and patient, as disciplinarian and offender. Interactions between parents and their children that are characterized by warmth, consistency, reciprocity, supportiveness, and openness have consistently been shown to be related to a range of positive outcomes. For example, children who report having a positive relationship with their parents tend to have higher self-esteem, have more positive peer relationships, do better in school, and avoid behaviors such as substance use and delinquency. In fact, the relationship between a parent and his or her child may be one of the most crucial factors in the personality growth of the child, and the quality of that relationship may determine how susceptible the child is to deviations in normal development. Moreover, despite the popular notion that parents become increasingly irrelevant during adolescence, there is a growing body of evidence that suggests parents remain a constant, meaningful influence on their teen's attitudes and behaviors well through the adolescent years.

As children grow, the balance of the components of a successful parent–child relationship modifies to account for changing physical, socioemotional, and cognitive needs of both the child and the parent. Indeed, an interactional style successfully used by a parent and a 5-year-old may be perceived quite differently if used by a parent and a 15-year-old. Although the nature of the parent–child relationship changes with time and development, there are several static but key essentials to a healthy and protective relationship from

childhood through adolescence. Two of these critical components are attachment and communication.

### Attachment

#### *Historical Perspective*

Attachment, simply defined, is the inclination for one individual to seek closeness with another individual (e.g., parents, romantic partner), to feel safe when that person is present, and to feel anxious in his or her absence. From the time they are born, children begin to form an attachment with their caregivers. Early in development, children learn what to expect from their parents: “If I cry, I will be comforted (or I will not be comforted),” or “if I am hungry, I will be fed (or I will not be fed),” or “if I smile, I will be smiled at.” Based on their experiences and interactions, according to attachment theory, the child will create a “map” (i.e., a “working model of attachment”) of what to expect when interacting with the parent. This map will then help guide future interactions between parent and child.

John Bowlby and his colleagues believed that children could be classified into one of four categories of attachment based on the working models the child created regarding his or her interaction with the parent: (1) secure, (2) anxious-ambivalent, (3) anxious-avoidant, and (4) disorganized. Each of the four types of attachment were thought to reflect certain strategies the child would use either to draw a caregiver closer or to dismiss or devalue the importance of the caregiver. There is strong evidence that secure attachment with a parental figure in childhood leads to greater emotional regulation, less personal distress, higher levels of social support, and better overall psychological

adjustment in adolescence. Conversely, insecurely attached children (i.e., those classified as anxious-ambivalent, anxious-avoidant, or disorganized) tend to have greater difficulty regulating negative affect, have poorer peer relationships, and exhibit greater levels of psychopathology.

Whereas many perceive attachment to be a static phenomenon established in infancy and maintained throughout childhood, research suggests otherwise. Attachment is a dynamic, interactive aspect of parent–child relations that is constantly adjusting and shifting throughout the life course. Indeed, attachment is not simply the product of a child’s perceptions of his or her caregiver’s early behavior; parent behavior toward the child is, in part, influenced by the child’s own behavior. As such, attachment is a product of ongoing interaction; children update their working models of attachment—and subsequently their behavior toward their parents—based on the quality and nature of the interactions. Parents, in turn, adjust their behavior toward their children based on the quality and nature of the interaction with their children.

### ***Parent–Child Attachment in Adolescence***

Historically, parent–child attachment has been discussed in the context of infancy and toddlerhood; however, attachment is an equally important dimension of the parent–adolescent relationship. As is the case in childhood, secure attachment to parents during adolescence is related to fewer mental health problems, less involvement in risky behaviors, better relationships with peers and romantic partners, and better strategies for coping with difficulties. Nevertheless, how attachment works in adolescence is less straightforward than in infancy and childhood.

Adolescents face many critical developmental tasks, including seeking autonomy from parents while increasing reliance on peers. Common sense might suggest that such a developmental task is incompatible with maintaining a secure attachment with parents. Contrary to this view, adolescents who successfully navigate this task are often keenly attentive to the importance of an ongoing relationship with their parents and to how that relationship may provide a critical bridge between dependence and autonomy. So how do adolescents achieve secure attachments with parents while simultaneously seeking autonomy?

One way is by walking a fine line between achieving their own agenda of obtaining autonomy and

maintaining certain objectives within their relationships with their parents. Within this so-called goal-corrected partnership, secure adolescents seek autonomy yet are still attentive to the need to maintain a stable, trusting relationship with parents. When there is a disruption within the parent–adolescent relationship, such as high conflict or a breach of trust, the adolescent makes corrections in order to reestablish the relationship. The result, therefore, is limited negative interactions, greater support within the parent–adolescent relationship, and greater levels of trust. This family environment allows the adolescent more opportunities to seek and establish meaningful, positive peer relationships in two ways. First, secure attachment with parents serves as a model for other relationships; this often translates into having secure peer and romantic partner relationships. Second, adolescents who have the trust and support of their parents are afforded more opportunities to engage in appropriate peer relationships, social activities, and environments outside of the home that promote autonomy.

### **Parent–Child Communication**

Another key element underlying strong and protective parent–child relations throughout the course of childhood and adolescence is the extent to which parents and adolescents talk openly and honestly with one another. Both the quality and the content of parent–adolescent communication serves as the framework upon which values and expectations are shared, information seeking and monitoring are influenced, and explanations and deeper understanding of behavior are obtained. Related to the attachment process, this communication framework is built from the beginnings of life and transforms with time.

Being able to discuss one’s intentions, plans, and activities without being criticized or punished promotes greater understanding for both the parent and adolescent roles. The sharing of values and expectations decreases the possibility of conflict in the relationship by increasing mutual understanding and eliminating confusion around established rules and roles within the family. As a result, parents may be more comfortable and efficient in situations where they can grant moderated independence, while adolescents are more likely to abstain from behaviors perceived to drift away from the parents’ values and expectations.

Communication also provides protection in terms of collecting increased amounts of information about the

adolescent's current activities, peers, and locations. Parents use varied approaches for increasing their awareness of their children's activities, yet one of the most effective means of increasing parent awareness is by collecting information directly from the adolescent (self-disclosure). Warm relationships and open communication between parents and their children are integral to increasing the likelihood that adolescents will feel comfortable enough to self-disclose information about their plans and activities to their parents.

Finally, there is a natural tendency for parents and adolescents to investigate situations in which they perceive most others to engage. Parents may investigate monitoring or parenting behaviors that may seem off center with their current relationship with their adolescent. Likewise, adolescents may find themselves in situations of which their parents disapprove. In both instances, the establishment of open communication increases the opportunity for each to discuss their behaviors. Understanding why someone engages in an activity decreases perceptions that the behavior was done in malice toward the other or as a result of the lack of trust or sense of privacy. Likewise, while challenging the warm and open parent-adolescent relationship, these situations require parents and adolescents to build from their relationship to react and communicate with one another effectively. A breakdown in communication in reaction to a challenging situation could alter all of the remaining protective processes (e.g., monitoring) that depend on an open communication between parents and adolescents.

Additional prevention against adolescent risk involvement or problematic parent reactions has been found in parent and adolescent discussions of particular issues. Conversations about sensitive topics such as community drug use or teenage pregnancy have been shown to decrease adolescents' drug use or sexual involvement. While most effective if started in a natural conversation while engaging in a different activity rather than being premeditated, these conversations have been shown to increase parent and adolescent awareness of these issues, to directly align parent and adolescent values with regard to participation in these behaviors, and to identify successful ways to avoid these behaviors in the future.

### Critical Factors

The strength and quality of parent-child relations can provide powerful protection against a range of

negative outcomes for adolescents. Whereas peers become increasingly relevant over the course of adolescence, parents continue to have a significant amount of influence on the attitudes and behaviors of their children. The key to this relationship is for parents and adolescents to be aware of the necessity to build and maintain strong, secure attachments and to communicate thoughts, plans, and experiences on a consistent basis. Moreover, both the parent and the adolescent must be aware that the bidirectional nature of the parent-adolescent relationship requires consistent appraisal and alteration to allow for the changing developmental needs of both parties. Finally, parents and adolescents should be aware that maintaining secure attachments and positive communication between parents and children during the adolescent years is not incompatible with the goal of achieving autonomy from parents; rather these may be critical factors leading to the successful attainment of that goal.

## PARENTING

---

The term *parenting* refers to the process of raising a child, usually from birth up until adulthood. A child's biological parents typically assume the parenting role and the majority of responsibility associated with raising a child. However, other individuals including stepparents, grandparents, foster parents, older siblings, adoptive parents, and other relatives may also be involved or even assume the primary role in parenting. The process of parenting involves providing education to children to teach them right from wrong and to foster their growth and maturation.

Parenting has been a topic of interest to researchers for decades. In particular, researchers who study child development have examined the relationship between parenting and child behavior. Many of these researchers have determined that it is more helpful to look at overall parenting styles than individual behaviors such as yelling as a form of discipline or playing games with their children. Parenting styles refer to a set of similar practices and strategies that parents use when attending to and disciplining their child. These styles incorporate two important components, responsiveness and demandingness. Parental responsiveness, also known as parental warmth, refers to how parents nurture and support their child's growth, individuality, and specific needs. Parental demandingness, which can also be referred to as behavioral control, describes the nature of the responsibilities that parents place on their child. For instance, some parents set high standards and expectations for their children, while other parents have few standards and expectations.

The manner in which parents help their child develop is predictive of child behavior and emotional functioning. In particular, the four parenting styles of authoritative, authoritarian, permissive, and uninvolved have been found to be related to specific outcomes in children. Therefore, numerous parent-training programs have been developed for diverse populations to target parenting styles. Research demonstrates that these programs are effective at improving parenting and reducing child behavior problems. As a result,

parent-training programs are becoming more widely available and are used for prevention as well as early intervention in and treatment of child mental health problems.

## Parenting Styles

Diana Baumrind conducted research on parenting styles by watching parents interact with their preschool-age children. Based on these observations, she identified three different parenting styles that describe and categorize parents based on both parental responsiveness and demandingness. She referred to these styles as authoritative, authoritarian, and permissive. Later Eleanor Maccoby and John Martin developed a fourth style, uninvolved or neglectful parenting. All of these styles are based on the assumption that parents' main responsibilities are to influence, teach, and manage their children. It is also important to note that all four styles are used to describe typical differences in all types of parenting and are not generally used to describe abusive parenting.

### *Authoritative Parents*

According to Baumrind's description, an authoritative or democratic parent is both responsive and demanding. Specifically, an authoritative parent is firm when necessary to enforce rules, but does so in the context of a warm and loving environment. These parents are able to recognize their child's individual needs, opinions, personality traits, and interests. Therefore, although authoritative parents monitor their children and have very clear rules and expectations, they are not overly intrusive or restrictive. They typically make reasonable demands on their child, given their child's age and developmental level. For instance, authoritative parents would encourage family discussions and value their child's point of view.

### *Authoritarian Parents*

Baumrind used the term *authoritarian* to describe parents who use a lot of behavioral control. However, this type of parent uses this control without the warmth characteristic of an authoritative parent. Authoritarian parents are similar to dictators in that they value and demand complete obedience in their children and believe that children should be kept in their place. This type of parent places many responsibilities on their

child and does not allow the child to make individual choices or decisions. Furthermore, an authoritarian parent may restrict discussions because of the belief that children should accept whatever their parents tell them.

### ***Permissive Parents***

According to Baumrind, a permissive, or indulgent parent, describes a parent who is warm but does not use behavioral control. Permissive parents are considered lenient because they do not place many responsibilities on their children and avoid exercising any form of power or control. Instead, permissive parents often try to reason with their children when the children misbehave. Children of permissive parents are essentially allowed to roam free and do whatever they desire. For instance, children of permissive parents may be able to eat whatever food they want and stay up as late as they want at night. These parents place few, if any, demands on their children and tend to avoid confrontations.

### ***Uninvolved Parents***

Maccoby and Martin added uninvolved parenting as a fourth style to describe individuals who are not particularly warm or demanding. Specifically, these parents place few expectations on their children and often do not respond to their child's needs. In general, these parents do not put much energy into child care beyond the effort required to provide for the child's basic needs (i.e., food, shelter). These parents often show little interest in and commitment to parenting. Sometimes this lack of interest and commitment results from issues such as parental depression, stress, and substance abuse that prevent the parent from assuming a more active role in parenting. Uninvolved parents can be indifferent to their responsibilities as parents and even rejecting or neglectful in extreme cases.

## **Parenting Styles and Child Behavior**

Parenting styles are important, because studies demonstrate strong relationships between parenting styles and child outcomes. Specifically, Baumrind and other researchers have found that these different parenting styles can be used to predict both child and adolescent behavior and adjustment. Therefore, researchers have learned which styles are associated

with positive outcomes and have even developed interventions to change parenting styles.

### ***Children of Authoritative Parents***

Research demonstrates desirable outcomes in children and adolescents of authoritative parents. They seem to be assured by both their parents' love and their parents' discipline. Typically, these children are well adjusted socially. They often have high self-esteem and perform well academically. Additionally, as a whole, they tend to have well-developed morals and few disruptive behavior problems.

### ***Children of Authoritarian Parents***

Research shows that children and adolescents of authoritarian parents often exhibit many behavior problems. Additionally, children of authoritarian parents tend to have poorer social skills, lower self-esteem, and higher rates of depression than other children. However, these children tend to display satisfactory academic performance.

### ***Children of Permissive Parents***

Studies suggest that children and adolescents of permissive parents often have more behavior problems and lower academic achievement than other children. However, these children tend to have better social skills, a higher self-esteem, and fewer depressive symptoms than other children. Overall, these children tend to be immature, disobedient, rebellious, and overly dependent on adults.

### ***Children of Uninvolved Parents***

Research shows that children and adolescents of uninvolved parents are at an increased risk for many negative outcomes. For instance, these children often have psychological and behavioral problems such as delinquent behavior, a low frustration tolerance, and poor emotional regulation. Additionally, they tend to have problems functioning socially and academically.

## **Parent Training**

Given the importance of parenting for child behavior, many treatment programs have been developed with the goals of improving parenting and reducing child

behavior problems. In particular, parent training programs have been developed to address the two main components of parenting styles, parental responsiveness and parental demandingness. Specifically, parents learn how to enhance their relationship with their child while increasing their expectations and standards. There are many different approaches and formats used in parent training; therefore, this entry only includes a general overview of parent training as well as brief descriptions of several programs.

### **Definition**

Parent training, a behavioral intervention, teaches parents skills and techniques they can use to modify their child's behavior. Historically, parent training has been primarily used in the treatment of child externalizing disorders such as oppositional defiant disorder (ODD), conduct disorder (CD), and attention deficit/hyperactivity disorder (AD/HD). However, parent-training programs also have been modified to help treat other childhood disorders, including anxiety, depression, and autism.

### **History**

Parent-training programs have changed over time. Early programs emphasized specific behavioral skills such as how to positively reinforce their children and use time-out. Gerald Patterson was one of the first persons to develop a complete program for families of antisocial children. Patterson's program was based on his theory that child disruptive behavior relates to the child's interactions with other members of the family. Specifically, Patterson's coercion hypothesis suggests that children who use disruptive behavior to get their way with adults will continue to escalate their disruptive behavior as long as the parent gives in to the child. Patterson's hypothesis also states that parents who try unsuccessfully to manage their child's disruptive behavior will develop more coercive parenting techniques such as nagging and temper outbursts. Therefore, Patterson developed a program to teach parents to give commands, use positive reinforcement for compliance, and enforce consequences by using a time-out. Later Constance Hanf developed a two-stage model that placed a greater emphasis on enhancing the parent-child relationship. The first phase of Hanf's program focused on parental responsiveness by teaching parents to play with their children, provide positive

attention for desirable behaviors, and ignore negative behaviors. The second phase of Hanf's model focused on parental demandingness. In this phase, parents learned how to give effective instructions and use time-out for noncompliance. Hanf's two-stage model has been adapted by many researchers for use with different populations.

## **Applications of Parent Training**

There are many different applications of parent training. These applications use different formats (e.g., group or individual sessions) and approaches to parent training (e.g., videotape modeling, coaching). In addition, these applications vary in the childhood problems they target and the appropriate child age range for treatment. The following is a brief description of several well-known and research-supported parenting-training programs.

### ***Forehand and McMahon***

Rex Forehand and Robert McMahon developed one of the first applications of parent training, a program called *Helping the Noncompliant Child*, based on Hanf's two-stage model. This treatment targeted parents of children ages 3 to 7 with disruptive behavior problems. This treatment typically was implemented individually and could be completed in about 10 weekly sessions. In the first phase of this program, parents were coached to use skills to strengthen the parent-child relationship, including providing specific praise for behaviors that they wanted their child to exhibit and ignoring or using selective attention for behaviors that they wanted their child to stop exhibiting. In the second phase, parents learned how to give direct commands and use time-out for noncompliance.

### ***Parent-Child Interaction Therapy***

Parent-child interaction therapy (PCIT), a parent training program also based on the Hanf two-stage model, was developed by Sheila Eyberg. PCIT was used originally to treat children ages 2 to 7 with disruptive behavior problems, but it has now been extended to other populations, including parents who are physically abusive, children with separation anxiety, and children with developmental delays. PCIT contains two phases: child-directed interaction (CDI) and parent-directed interaction (PDI). In CDI, parents learn skills to

increase their warmth and responsiveness through playing with their child. In PDI, parents learn to manage defiant and disruptive behaviors through giving effective instructions and using time-out for noncompliance. Both phases are taught by a therapist who coaches the parents while they play with their child using a bug-in-the-ear microphone device. PCIT is assessment-driven in that parent progression from CDI to PDI as well as termination from the program are based on child and parent mastery of skills as determined by weekly coding of parent-child interactions.

### ***Incredible Years Parent Program***

The incredible years parent program, developed by Carolyn Webster-Stratton, is another program designed for parents of young children with disruptive behavior problems. This program, also based on Hanf's model, is appropriate for parents of children ages 2 to 8 with either ODD or CD. The program uses a group format to teach parents behavioral skills through observing and discussing videotapes that depict parent-child interactions.

### ***Barkley***

Russell Barkley developed another program, similar to others based on the Hanf model, specifically to address the needs of parents of children with AD/HD. Barkley's program, typically completed in 9 to 12 sessions, is flexible, because it can be used in a group or individual format. In addition to learning behavior management skills, parents in this program are educated about AD/HD. This program can be used in combination with other treatments such as medication and social skills training.

### ***Triple P Program***

The triple P or positive parenting program was developed by Matt Sanders for parents of newborns to children 12 years old. This program differs from the other programs described above, because it is a prevention program. Therefore, parents learn behavioral management skills designed to prevent the onset of childhood emotional, behavioral, and developmental problems. The triple P program has different levels based on the focus of treatment. For example, the program is different when it is used with parents of infants than when it is used with parents of

preadolescents. Also, the program varies depending on whether it targets parents in the general population or specific parents with children at risk for behavioral problems.

### ***Common Sense Parenting***

Common sense parenting is another parenting program used with a wide range of children, specifically ages 2 to 16. This program was developed to emphasize effective behavioral management techniques used by Girls and Boys Town, a nonprofit organization that specializes in treating children who have been abused or neglected. Components of a typical session of this program include review, instruction, modeling, practice and feedback, and summary.

### ***Functional Family Therapy***

Functional family therapy (FFT), a family-based prevention and intervention program developed by James Alexander and Bruce Parsons, was designed to target the needs of older children, specifically youth ages 10 through 18. FFT emphasizes parent and adolescent communication in parents of youth with a variety of problems, including substance abuse and CD. Also, this approach can be used to treat youth who are at risk for these and other behavioral problems.

### ***Systematic Training for Effective Parenting***

Systematic training for effective parenting (STEP), a nine-session skills-based parenting program developed by Don Dinkmeyer and Gary McKay, is based on the work of Alfred Adler and Rudolf Dreikurs. Some of the specific skills taught to parents in STEP include learning to understand the behavior and misbehavior of children, provide encouragement, improve parent-child communication, hold family meetings, apply natural and logical consequences to child misbehavior, and improve parental confidence.

## PARENTING STRESS INDEX

---

The Parenting Stress Index, 3rd Ed. (PSI) is a norm-referenced test developed by Richard R. Abidin. The PSI assesses for dysfunction in the parent–child relationship and is based on a theory that the level of stress in the parent–child dyad is the result of child, parent, and situational characteristics. The PSI attempts to identify parental levels of stress, dysfunctional parenting dynamics, and childhood behavior problems. The measure assumes a direct interaction between parental stress and behavior problems in children. The PSI can be a useful assessment for therapists working with parents and families, abusive or at-risk families, children with adjustment or behavior disorders, and clients in forensics settings.

### Description of the Instrument

The PSI is a 120-item self-report questionnaire that assesses child and parent behaviors on a number of domains. It typically takes a respondent 20 to 30 minutes to complete the questionnaire. The PSI is normed for parents of children between 1 month and 12 years of age. One unique feature of the PSI is that it starts out as a behavior checklist on which a caregiver rates a child, but in the middle of the questionnaire, it becomes a self-report checklist where the parent rates him- or herself. Consequently the PSI has subscales that compose a child domain and a parent domain.

### Child Domain

The child domain assesses for characteristics displayed by children that make them difficult to parent. Subscales that compose the child domain include the following:

*Distractibility/hyperactivity scale (DI)*—This scale assesses behaviors that are consistent with attention deficit/hyperactivity disorder (AD/HD). It is possible for a parent to rate a child highly on this scale but the child does not qualify for a diagnosis of AD/HD. In those cases, explanations for the parent's high ranking may include the parent lacking the necessary energy to deal with a normal child, the parent being older and having difficulty adjusting to life with a child, or the parent having unrealistic expectations for the child's behavior.

*Adaptability (AD)*—This scale assesses a child's ability to adapt to changes in his or her physical or social environment. High scores on this domain are associated with the need for routine and distress with change often seen in children with autistic spectrum disorders. Children with high scores also tend to overreact to changes in sensory stimulation, avoid interacting with others, have difficulty being calmed when upset, and have difficulty forming meaningful relationships.

*Reinforces parent (RE)*—This scale assesses how reinforcing it is for a parent to be with this child. High scores suggest that the parent–child interaction fails to produce positive feelings. Possible explanations for this situation include that a child is impaired in his or her response capacity, the child is depressed, the parent is depressed and projecting negative appraisals onto the child, or the parent is misinterpreting or unable to understand the child.

*Demandingness (DE)*—The demandingness scale assesses a parent's perception that the child is placing unrealistic demands upon him or her. High scores are associated with ratings that describe a child as being unreasonable, impatient, and needy. The stress associated with perceptions of demandingness can be magnified if the parent is overly committed to being a model parent. High scores on demandingness can also be associated with separation anxiety in young children and oppositional and defiant behaviors in older children.

*Mood (MO)*—The mood scale assesses symptoms associated with depression. High scores are associated with children who cry frequently, are unhappy, and appear depressed. Children who score high on demandingness tend to also score high on the mood scale. With extremely high scores, one also needs to consider lack of parental attachment, parents being psychologically unavailable, and parental substance abuse.

*Acceptability (AC)*—The acceptability scale assesses parental expectations for the child's physical, intellectual, or emotional adjustment. High scores basically suggest that this child is not the child that the parents had hoped for with regard to these dimensions.

### **Parent Domain**

The parent domain assesses sources of stress and potential dysfunction in the parent. High scores are usually associated with parents who feel overwhelmed and inadequate in the task of parenting their child. It is not uncommon for young parents or parents with limited experience working with children to have elevated scores, although they seldom score above the 90th percentile.

*Competence (CO)*—Competence is associated with a parent feeling lack of acceptance and criticism from others for the way he or she parents the child. Parents of children with severe physical or mental disabilities often score high on this scale, but so do parents with limited prior parenting experience, parents who lack knowledge of normal child development, and parents who have discovered that having children is not as reinforcing as they thought it would be.

*Isolation (IS)*—This scale is associated with parents who feel socially or emotionally isolated from their support systems. When this score is high, there are often relationship problems between the child's primary caregivers. In addition, high scores are also associated with increased risk for child abuse and neglect.

*Attachment (AT)*—This scale assesses the degree to which a parent feels a sense of emotional closeness with the child. High scores are usually associated with cold parent-child interactions. The parent may also be impaired in his or her ability to perceive and understand a child's feelings and needs accurately. Low

levels of parental monitoring and vigilance are also often associated with high scores.

*Health (HE)*—The health scale assesses a parent's perception that his or her physical health is deteriorating. Parents with chronic medical disorders often score higher on this scale.

*Role restriction (RO)*—This scale assesses the degree to which a parent feels his or her freedom has been restricted by the child. Parents who score high have frequently been frustrated in their attempts to maintain their own identity since the child entered their lives. These parents often report feeling overly controlled or dominated by their child's demands.

*Depression (DP)*—The depression scale assesses for symptoms of depression in the parent. Parents who score high on this scale often report finding it difficult to mobilize the energy necessary to fulfill their parenting roles.

*Spouse (SP)*—This scale assesses how much emotional and active support the parent feels that he or she receives from the child's other caregivers. Individuals with high scores report feeling unsupported in their parenting roles. While a high score may reflect stereotypical sex roles, it usually reflects dysfunction in the caregiver's relationships.

The PSI also provides a total stress score, which is essentially an average of the stress ratings on the child and parent domains. There is also a life stress scale that is composed of 18 true-false questions related to the presence of significant life stressors in the past year. Finally the PSI has a defensiveness scale to detect parents likely to be minimizing their concerns.

### **Standardization**

The PSI was standardized on over 2,600 mothers with children between the ages of 1 month and 12 years. Only 200 fathers with children between the ages of 6 months and 6 years were included in the standardization sample. For this reason, when interpreting PSI data obtained from fathers, particular caution is recommended. The normative sample was not random or stratified and represents primarily a sample of convenience; most participants came from central Virginia. The ethnic composition of the sample was

approximately 76% Caucasian, 11% African American, 10% Hispanic, and 2% Asian. Most participants were married (76%), and 60% had some education after graduating from high school.

### Psychometrics

The reported internal consistency reliabilities for the PSI appear to be adequate. The coefficient alpha for the child domain was .90, with subscales ranging from .70 to .83. The coefficient alpha for the parent domain was .93, with subscales ranging from .70 to .84. For the entire scale, the coefficient alpha was .95. The test-retest reliability for the entire scale is reported to range from .65 for a one year interval to .96 for a 1- to 3-month interval.

With regard to content-related validity, most of the stimulus items on the PSI were included because empirical research found the attribute to be related to parental stress. Items have also been modified based upon feedback from mental health professionals. Evidence for criterion-related validity suggests that the PSI correlates in the expected directions with various related measures. For example, the PSI child domain score correlated .56 with the Achenbach Child Behavior Checklist. The proposed factor structure of the PSI was not strongly supported by the factor analytic studies reported in the manual. Over half of the child domain items and almost half of the parent domain items had factor loadings below .30 for their respective subscales. For this reason, more emphasis should be placed on evaluating the total stress scores than the individual subscale scores.

### Additional Products

The PSI has a computer scoring and interpretation program that gives the examiner unlimited uses. The interpretation provides a variety of plausible treatment recommendations for a family based upon the ratings. An additional feature that the computer interpretation provides is a comparison of a particular profile to the average profiles of individuals in various clinical groups. For example, a clinician can compare a parent's ratings with the ratings of parents who have a child with autism, of parents who have physically abused their child, or of teenage parents living in the inner city. There are approximately 30 clinical groups to which a client's profile can be compared.

There is also available a 36-item PSI Short Form. This abbreviated PSI measure gives different

subscales but assesses both parent and child domains. Finally there is another measure that is an upward extension for older children and adolescents ages 11 to 19 called the Stress Index for Parents of Adolescents (SIPA). While the subscales are not identical to those found in the PSI, the SIPA also assesses child and parent domains.

## PHRENOLOGY

---

Phrenology, an outmoded scientific discipline, predicted individual traits and characteristics in humans by analyzing the shape of the skull. Franz Joseph Gall, a Viennese physician practicing in the late 18th century, held that the brain shaped the skull, and the resulting bumps and ridges could be used to predict human behaviors, aptitudes, and tendencies. Gall originally hypothesized 27 phrenological "organs." For example, the region above the right eye was used to predict perceptive intellect, and therefore someone with a large protuberance in this area was thought to demonstrate keener insight than those who either lacked a bump or possessed a lesser one.

If Gall was the father of phrenology, J. G. Spurzheim was its first son. Together, their research, publications, and lectures expanded phrenology in Europe. In Great Britain, George Combe became an important advocate and wrote prolifically on the topic. Phrenology left the relative obscurity of the medical literature, and mainstream phrenological societies were formed across Europe. The movement made its way to the United States upon the establishment of the Philadelphia Phrenological Society in 1822.

This success and growth was to be short lived, however. By the mid 1800s, phrenology was losing ground and being dismissed as mere divination.

However, phrenology made lasting contributions to science and set the stage for linking psychology and neurology to create a study of the different functions and utilities of the brain. Additionally, psychology and medicine were moved toward a monistic theory of mind and body. In other words, the mind and body came to be viewed as one entity in opposition to the prevailing dualistic theory that the mind and body were inherently separate.

To the modern student, the basis of phrenological theory might appear archaic. Although phrenology is now abandoned as a scientific method, some of its presuppositions remain paramount. For example, the idea that different parts of the brain account for varying functions of behavior and character remains routine in present neurology and psychology.

The localized psychological and cognitive processes of the brain are still only partially defined. The current neurological mechanisms used to understand this potential localization remain less than accurate. In its time, phrenology endured an upsurge of criticism primarily as a consequence of its theoretical exploration into brain functions. Phrenology postulated numerous ideas about the impact of these still-theoretical, exclusive areas of the brain and in many ways remains the theoretical mother to the scientific study of the mind.

## PLAY THERAPY

Play therapy can be defined as a cluster of theory-driven treatment modalities used to establish an interpersonal process wherein trained play therapists help clients prevent or resolve psychosocial difficulties, facilitate optimal development, and reestablish the ability to engage in adaptive play behavior. For more than half a century, it has been the most prevalent child mental health therapy in the United States. While play therapy is traditionally implemented with children ages 3 to 12, many play therapy techniques (e.g., tray construction with miniature objects) are also used as therapeutic interventions with teenagers and adults. There is no single play therapy approach; instead, there are several prominent theoretical schools of thought and numerous play therapy techniques. Though play therapy is most often used as an individual therapy, it is also implemented via group play therapy and family play therapy. Often, professional therapists conduct the play therapy, but parents and other care providers can also be taught to perform play therapy. The following play therapy overview includes discussion of the definition of play, the therapeutic use of play, play therapy history, play therapy outcomes, and play therapists' qualifications.

### Definition of Play

Although there are multiple definitions of play, it is generally considered to be an activity that is intrinsically motivated, freely chosen, nonliteral, actively engaged in, and pleasurable. In contrast, children with psychological disturbances often exhibit play that is compulsive, impulsive, irrational, and devoid of pleasure. Play has been called the singular central activity of childhood. It occurs in virtually all cultures and circumstances.

Given the prevalence of children's play, it is often seen as integral in human development. Jean Piaget described play as "a process that allows children to mentally digest experiences and situations." Play is fundamental in children's development of expressive language, communication skills, emotional development, social skills, decision-making skills, and cognitive development. The functions of play have been classified into four categories: biological (learn basic skills, relax and release excess energy, kinesthetic stimulation and exercise), intrapersonal (mastery of

situations, mastery of conflicts), interpersonal (develop social skills, separation-individuation), and sociocultural (imitate desired roles).

### Therapeutic Use of Play

Play has been described as a form of self-therapy for children. Through play, children have the opportunity to work through conflicts, relieve anxieties, and make sense of their worlds. Consequently, play functions well as a facilitative force in children's therapy. A goal of play therapy is to help disturbed children work through their issues, so they can experience pleasurable play again.

Researchers have identified specific qualities of play behavior that facilitate the therapeutic process (i.e., communication, relationship enhancement, creative thinking, overcoming resistance, catharsis, abreaction, role-play, fantasy/visualization, metaphoric teaching, attachment formation, positive emotion, mastering developmental fears, game play) and the accompanying beneficial outcomes (working alliance, understanding, self-esteem, innovative solutions to problems, emotional release, adjustment to trauma, practice/acquiring new behaviors, empathy, fantasy comprehension, insight, attachment, self-actualization, self-esteem, growth and development, socialization).

### Play Therapy History

Documentation of psychotherapy with children reaches to the early 1900s. Early records describe Sigmund Freud's work with Little Hans's father in the attempt to alleviate Hans's phobic reaction. Play was first directly applied to children's therapy in 1919 through Hermine Hug-Hellmuth's utilization of play for child assessment and treatment and analysis. Anna Freud began using play in 1928 as a way of building therapeutic alliances and enticing children into the process of analysis, and in 1932 Melanie Klein proposed using play as a substitute for children's verbalizations. These early forms of psychoanalytic play therapy were focused on the attainment of insight through interpretation of the child's play.

A variety of play therapy theories and techniques were developed and refined between the 1930s and 1950s, including psychoanalytic and goal-oriented *structured therapy* in the late 1930s; David Levy's 1938 *release therapy* for trauma treatment; Joseph

Solomon's 1938 *active play therapy* for impulsive acting-out children; Gove Hambridge's 1955 directed abreaction reenactment procedures; and the relationship therapies of Jessie Taft (1933), Frederick Allen (1942), and Clark Moustakas (1959). Carl Rogers's client-centered approach, developed in the 1940s, was modified into child-centered play therapy by Virginia Axline in 1947. This nondirective form of play therapy has come to be referred to as *traditional play therapy*.

In the late 1960s, Ann Jernberg developed an approach focused on recreating and fostering healthy parent-child attachments called *theraplay*. Bernard Guerney's 1964 *filial therapy* was designed to involve parents in the play therapy process. Constance Hanf developed a two-stage model in the early 1970s that became more well known in the 1990s as parent-child interaction therapy (PCIT). Viola Brody's 1978 *developmental play therapy* emphasizes the use of physical contact and semistructured sessions. Kevin O'Connor developed an approach that integrates a cognitive developmental framework and an ecosystemic perspective into *ecosystemic play therapy*.

The significant contributors throughout the history of play therapy have produced an abundance of approaches, including psychoanalytic, client-centered/humanistic/nondirective/traditional, behavioral, cognitive-behavioral, family, developmental, Adlerian, gestalt, reality, time-limited, theraplay, fair play, ecosystemic, and dynamic.

### Outcomes

It is important to demonstrate the effectiveness of play therapy to justify practice, provide court testimony, and receive third-party insurance payments. The widespread use of play therapy dictates that its effectiveness ought to be clearly established. However, there is ongoing controversy among researchers regarding how well play therapy works. Play therapy critics have asserted that there is not an adequate research base to demonstrate the efficacy of play therapy, largely due to small sample sizes, case studies, and anecdotal reports. In particular, critics cite too few well-defined and well-executed empirical studies evaluating the efficacy of play therapy.

Part of the efficacy controversy seems to stem from epistemological differences between positivist, empirical traditions and naturalistic, qualitative paradigms. Empirically based clinical studies have a well-established reputation in the field as hard research, but

qualitative traditions are still suspect by some researchers' values.

Others state that case studies can lend credibility to the effectiveness of play therapy. Sue Bratton and Dee Ray reviewed over 100 case studies that document effective results with play therapy treating children with a wide variety of therapeutic concerns. They also reviewed 82 experimental studies of play therapy and concluded that play therapy demonstrated effective results in treating self-concept, behavioral change, cognitive ability, social skills, and anxiety.

A meta-analysis of 94 play therapy efficacy studies by Ray and her colleagues found that play therapy is a helpful intervention in child psychotherapy. The authors summarized that play therapy worked in a variety of settings across modalities, age, and gender with clinical and nonclinical populations, and across various theoretical schools of thought. Not only did this research report the positive effect of play therapy, the overall effect size was in the large effect range.

This meta-analysis confirmed two findings previously reported by Michael LeBlanc and Martin Ritchie: Parental involvement significantly improves the effectiveness of play therapy, and the effectiveness of play therapy increases for up to 35 to 45 sessions. (At 45 sessions, effectiveness levels started to decline.) A 2005 meta-analysis of 93 controlled play therapy outcome studies also supported LeBlanc and Ritchie's research that maximum effect size was reached between 35 and 40 sessions and that involving the parents and using humanistic treatments resulted in more positive effects. Through a meta-analysis of 42 play therapy outcome studies, LeBlanc and Ritchie found maximum effect sizes between 30 and 35 sessions. While most research indicates greater gains from a larger number of sessions, significant positive results have been reported for as few as 12 to 15 child-centered play therapy sessions.

Finally, Ray and her colleagues concluded that through the use of further experimental studies with specific measures and clear definitions, play therapy research has adequately addressed the critics' concerns regarding the efficacy of play therapy, small sample sizes, case studies, and anecdotal reports. They recommended that play therapy researchers (a) produce more research on the immediate and long-term effects of play therapy, (b) compare play therapy to other child psychotherapies, (c) explore the optimal number of sessions, (d) examine the most appropriate issues

addressed by play therapy, (e) determine the most accurate outcome measures, and (f) utilize specific play therapy protocols so replication is more easily achieved.

## Training and Qualifications

Before providing play therapy, it is important to be qualified to do so. Ethical guidelines require that professional counselors provide competent services and not advertise or practice beyond their levels of training. Certainly there are qualified professionals who provide play therapy services who are not registered play therapists. At the same time, especially if play therapy is a major part of one's practice, it is wise to seek the highest level of training possible. The Association for Play Therapy (APT) is the primary organization that provides professional standards for play therapists. The APT is also referred to as the International Association for Play Therapy (IAPT) and is responsible for publishing the *International Journal of Play Therapy*. In 1982, Charles Schaefer and Kevin O'Connor cofounded APT to provide a forum for professionals interested in helping children through play therapy. Professionals interested in learning more about becoming registered play therapists (RPTs) or a registered play therapist supervisor (RPT-S) can find the necessary information at APT's Web site.

## Summary

The play therapy field includes a group of interventions with a rich history and a continually developing vision of how to best treat children's mental health needs. From the helping field's first pioneers to today's professionals, play has been employed as a natural tool to assist children in working through a wide range of issues. Because play is an activity with which most adults are familiar from their own childhood, some helping professionals without play therapy training erroneously assume that they can use play to effectively help children. Though playing with a child may be enjoyable, it may not be therapeutic. Thus, the more training and supervision play therapy professionals receive, the greater the likelihood of treatment success. As with all psychological interventions, play therapy can benefit from more rigorous research. This not withstanding, there are certainly a number of noteworthy studies that point to the helpfulness of play therapy.

With its long history and promising outcomes, play therapy will likely continue to evolve and be used as a primary intervention with children for decades to come.

## POSTDEGREE/PRELICENSURE SUPERVISION

Counselors have been eligible for licensing beginning in 1973 in Virginia. Currently, all states with the exception of Nevada and California have licensing, and there is considerable variability as to required credits, course titles and topics, and pre- and postgraduate hours of supervision. Credit requirements range from a master's degree (no credit hours specified) to 60 credits, with the majority being 45 to 48 credits. Supervision requirements vary from a low of 1,000 hours to a high of 4,500 hours, with the majority being 3,000 hours.

The purpose of this entry is to explore the purpose, definition, process, and ethics of the practice of prelicensure clinical supervision. While there are multiple definitions of supervision, the unifying theme is to assist the new counselors in applying their training with increasing effectiveness through careful observation, analysis, education, redirection, coaching, and mentoring by a seasoned, licensed professional. Some form of supervision occurs across all levels of applied social science and medicine.

### Supervision Defined

The Council on the Accreditation of Counseling and Related Educational Programs (CACREP) specifies the hours and functions of supervision in counselor preparation. However, in non-CACREP accredited programs, the approach to supervision may or may not be made explicit. Either way, a brief overview of the purpose and definitions of supervision is presented as a starting point.

Supervision is an intervention provided by a more senior member of a profession to a more junior member or members of that same profession. This relationship is evaluative, extends over time, and has the simultaneous purposes of enhancing the professional functioning of the more junior persons, monitoring the quality of the professional services offered to the clients they see, and serving as a gatekeeper for entry to the particular profession.

Supervision is a type of intervention that although distinct from the provision of counseling or psychotherapy, is a change agent in the development of a new professional. While supervision does include an educational component in the form of a predetermined curriculum for all students, supervision is tailored to

meet the unique developmental needs of the individual or group of supervisees. Although there may be points in the supervisory process where a supervisee's personal issues are addressed in relation to the clinical work, the supervisor does not engage in a therapeutic relationship with the supervisee to resolve these issues. Rather, the issues are addressed in a manner that heightens the supervisee's awareness of how these factors may affect his or her work with clients. It is the supervisor's responsibility to hold the supervisee accountable for effectively managing client issues and providing appropriate referrals. There is a distinction between consultation and supervision, where supervision is generally imposed by licensing requirements of the postgraduate/prelicensed counselor, while consultation is sought freely by the clinician, perhaps on a single occasion, and not necessarily from a member of his or her own discipline. Additionally, there is no evaluative component involved in a consultative relationship.

### **Postgraduate Supervision**

Supervision, required by counselor licensing and regulatory bodies, is provided by a senior member of a profession (who, at a minimum, is licensed) for a junior member of the same profession working toward licensing. Although various disciplines can aptly address theoretical orientations, skill set development, and case management skills, socialization into the profession and fostering a sense of professional identity come from within a discipline. Supervision involves assisting the new professional in attending to matters of professional importance, e.g., changes in licensing laws, third-party reimbursement, modification or issuance of practice guidelines. Moreover, it includes not only bringing such matters to the supervisee's attention but also developing the knowledge of how and what to attend to, finding sources of information pertinent to the profession, and participating in organizations relevant to the profession, i.e., the American Counseling Association and state branches.

Currently, supervision standards vary and may or may not require someone licensed from the same discipline, a licensee, or an approved supervisor credential such as the Approved Clinical Supervisor (ACS) credential from the Center for Credentialing Education (CCE) of the National Board for Certified Counselors (NBCC). Requirements about the length of time and hours of supervision required for licensing vary across states and territories. However, one

common practice is that the postgraduate counselor must be under supervision until licensed in order to practice independently. The supervisor is required to provide ongoing evaluation of the postgraduate counselor and to submit or withhold a recommendation to license the supervisee.

### **Models of Clinical Supervision**

Supervision is provided in various models and is often tied to a theoretical orientation, ranging across psychodynamic, developmental, narrative, cognitive-behavioral, person-centered, and eclectic/integrationist. Although supervisees often have little choice in the model of supervision they receive, new counselors should seek varying models and find supervision that best meets their theoretical orientation and needs and the needs of the clients with whom they work. Supervisors have an ethical obligation to encourage new counselors to explore several theoretical orientations rather than follow only the supervisor's model.

### **Ethics and Competency to Practice**

New counselors may have less day-to-day supervision during employment than in their internship and can benefit from the supervisor's knowledge in areas that provide a potential ethical slippery slope. Because of the varying levels of preparation and professional orientation, constant reference to a code of ethics in clinical supervision is essential. Addressing such issues as insurance payments, boundaries, and multiple relationships can start the new counselor off in a healthy ethical direction.

Supervisors also have a responsibility to insure that supervisees are employing the most current and effective practices and should be thoroughly familiar with the research on empirically supported treatments. Most licensing laws and regulations include a caveat that counselors provide services in areas in which they are trained. Therefore, clinical supervision should focus on the competency of supervisees in providing services or addressing client issues consistent with their training. When practicing outside the boundaries of their competency, additional supervision, training, reading, and regular consultation or referral can ensure ethical practice and prevent licensing violations. Licensure candidates must be knowledgeable of the scope of practice in their state, because states with the broadest language include "diagnose and treat," while other states have more restrictive language.

## Multicultural, Gender, and Sexual Orientation Sensitivity

Supervision, like counseling, requires an awareness of, and competency in, multicultural, gender, and sexual orientation issues present in the process. Most supervisors are White, middle class, and of European origin, and studies about the impact of multicultural supervision are limited. Multiculturally based supervision offers a conceptual framework, and supervisees benefit from a variety of supervisors who provide a diversity of cultural, racial, gender, and sexual orientation backgrounds. Counselors graduating from a CACREP accredited program are required to study multicultural counseling and have field experiences in a range of multicultural settings. Most licensing boards use the CACREP course distribution, requiring social and cultural competency. Thus, supervisees should be encouraged to continually assess their multicultural competencies relative to CACREP's multicultural counseling competencies and standards.

## Recommendations to Licensure Candidates

Because standards vary and the portability of licenses is not assured, new graduates should familiarize themselves with the supervision requirements of the state in which they intend to seek licensure. With regulations frequently changing, candidates are advised to continually check for modifications in requirements. Because the supervisor's role in licensing is critical, candidates should seek supervision from someone who is experienced and thoroughly versed in licensing requirements.

Finding a supervisor is often dependent on regulatory boards that provide a list of qualified supervisors. If there are no requirements, supervisees can find qualified counseling supervisors through their professional associations (ACA and state branches) or graduate programs. The American Association of State Counseling Boards (AASCB) is working to develop common standards among states by adopting a nationwide portability document and establishing the National Credentials Registry (NCR) to assist prelicense counselors with supervision documentation.

Interviewing potential supervisors can provide insight into their theoretical orientation, counseling identity, supervision model, and availability. New counselors should look for personal qualities in the

supervisor such as enthusiasm, a positive attitude, and openness to diversity as indicators of the potential for developing the working alliance between supervisor and supervisee. Ideally, seeking some, if not all, supervision from a licensed professional counselor will ensure a strong counseling identity and contribute toward future ethical practice.

## POSTDOCTORAL TRAINING

---

At present, postdoctoral supervised experience is required for licensure in most states, for some forms of institutional employment, and for board certification (e.g., American Board of Professional Psychology) in many specialty areas. However, there is ongoing debate regarding the requirement for postdoctoral hours for licensure as well as the definition of postdoctoral training itself. Recent years have witnessed a series of conferences related to postdoctoral education and training, the development and implementation of accreditation guidelines for postdoctoral training programs, and recommendations from the American Psychological Association (APA) to eliminate the postdoctoral requirement. There is variability in existing formalized programs in terms of accreditation status, funding, training focus, structure, and setting. The decision for students regarding seeking formalized postdoctoral training remains complicated, and individuals need to consider the most appropriate postdoctoral experience for themselves given their professional and personal goals.

### History

Postdoctoral training, or training that occurs following the receipt of the doctoral degree, has been the subject of long debate within psychology. The requirement for postdoctoral training dates back to the 1949 Boulder conference, during which conference participants asserted that to become proficient in psychotherapy, postdoctoral training would be needed. The value of postdoctoral training was further affirmed at the 1955 Stanford and 1958 Miami conferences; however, there was no consensus that it should be a required part of the education and training sequence. It was at the Chicago conference, held in 1965, that postdoctoral training was conceptualized as

a vehicle for securing advanced and specialized competence.

It was not until 1972, however, that the first conference devoted specifically to education and training at the postdoctoral level was held at the Menninger Clinic. However, no specific guidelines for postdoctoral training were devised. At the 1973 Vail conference, some attention was paid to postdoctoral training related to continuing professional development and to matters of access and flexibility. At the 1987 National Conference on Graduate Education in Psychology, conference participants concluded that narrow specialization most appropriately occurred postdoctorally. At the annual APA convention in 1990, there was a meeting to discuss a model for a national program of psychology postdoctoral training that would be offered through comprehensive psychology postdoctoral centers of excellence.

Some of the most ardent supporters for accreditation at the postdoctoral level were individuals in the specialties. Throughout the 1980s, guidelines were developed for postdoctoral training in various specialty areas, such as health, clinical child psychology, and clinical neuropsychology. In 1992, in response to concerns expressed at national conferences (e.g., the Gainesville conference) regarding the lack of consistency in internship training in the postdoctoral experience and to calls articulated by the Joint Council on Professional Education in Psychology (JCPEP) for general standards in postdoctoral training and formal specialty certification, the first National Conference on Postdoctoral Training in Professional Psychology, cosponsored by APA and the Association of Psychology Postdoctoral and Internship Centers (APPIC) was held in Ann Arbor, Michigan. Conference participants crafted a policy document that addressed the purposes of postdoctoral training; entrance requirements; program content, structure, and organization; faculty-staff; and evaluation mechanisms. They developed recommendations for initiatives to foster excellence and innovation in postdoctoral education and training and called for guidelines and principles for accrediting postdoctoral programs.

In 1994, the APA held a National Conference on Postdoctoral Education in Psychology in Norman, Oklahoma. Attendees provided models for postdoctoral and continuing education and training to develop and enhance the competence necessary for psychologists to contribute maximally to teaching, research, and practice; established a taxonomy and terminology

to describe postdoctoral and continuing professional education and training; proposed mechanisms for documenting program adequacy and trainee competence; identified and developed funding opportunities; and delineated the requisite steps to implement conference models for postdoctoral and continuing education and training.

### ***Development of National Standards***

APPIC first began accepting postdoctoral programs for membership in 1974–1975, and it established specific postdoctoral membership criteria in 1987. By the end of 2006, there were 103 APPIC-member postdoctoral programs. A subset of these programs receives APA accreditation. The current APPIC membership criteria for postdoctoral training programs include a planned and programmed sequence of training experiences, an appropriately qualified licensed psychologist as training director, two or more qualified and licensed psychologists on staff or faculty, 2 hours or more per week of individual supervision, additional hours of learning activities, and a requirement that candidates spend at least 25% of their postdoctoral fellowship time in professional psychological services. Programs must include a minimum of 1,500 hours of total time and can be completed on a full time or part time basis. Depending on the area of specialty, the program may be longer than 1 year in duration.

From the mid-1980s forward, there were calls for accreditation standards for postdoctoral training, and subsequently in the early 1990s, the Inter-Organizational Council for the Accreditation of Postdoctoral Training Programs (IOC) was formed. The IOC, in coordination with APA's Committee on Accreditation, developed generic guidelines and procedures for accrediting postdoctoral programs that were formally adopted in 1996 by the APA Council of Representatives. Postdoctoral programs were first accredited by APA in 1997. As of July 2006, there were 26 accredited postdoctoral residency training programs and 20 accredited specialty practice programs; some sites have more than one accredited program.

Typically, accredited postdoctoral programs are 1 year in length, except that certain specialty areas (e.g., clinical neuropsychology) require 2 years. Some specialties, notably neuropsychology, have a national organization representing their postdoctoral programs. For some specialty areas, APA's Council of

Specialties has augmented general accreditation guidelines with specialty-specific guidelines.

Despite efforts to develop national standards, most programs fall outside of the APPIC and APA system, and thus there is insufficient quality control for many programs. There also is a lack of consistent incentive for programs to seek APPIC membership or APA accreditation, because it is not an expectation of licensing boards nor is it the norm (except for Department of Veterans Affairs medical centers and in certain specialty areas). This state of affairs also makes it difficult to accurately depict the number and types of postdoctoral programs available in North America.

### ***Licensure***

The past 20 to 25 years have witnessed dramatic shifts with regard to licensure requirements. In 1985, 28 states required postdoctoral experience for licensure. In 2007, 48 states require postdoctoral experience. However, jurisdictions vary with regard to the clinical and supervisory requirements of the postdoctoral experience, number of hours that constitute a training year, and length of time required to, and allowed to, complete training. Information on postdoctoral requirements by jurisdiction can be found at the Association of State and Provincial Psychology Boards' Web site. The growth in the number of states requiring supervised work experience at the postdoctoral level for licensure was in response to the 1987 model act for state licensure of psychologists, in which APA recommended 2 years of supervised professional experience for licensure, 1 of which needed to be postdoctoral.

The requirement for the postdoctoral year for licensure was questioned by the Commission on Education and Training Leading to Licensure, established by the APA Council of Representatives, which met in 2000. The commission recommended retaining the 2-year experience requirement but argued for increased flexibility in the timing and sequencing of this experience. While the requirement for the internship was endorsed by commission members, they stated that the second year of experience could be obtained either through a preinternship practicum or postdoctoral experience. However, participants acknowledged that it was essential that the profession study the requisite competencies for licensure and determine when in the education and training sequence such competencies were obtained. There has been an active movement focusing on these competencies and their assessment in the past 5 years.

In an effort to implement the recommendations of the Commission on Education and Training Leading to Licensure, in February 2006, the APA Council of Representatives passed a statement recommending that for licensure, applicants must demonstrate that they have completed a sequential, organized, supervised professional experience, equivalent to 2 years of full-time training, that can be completed prior or subsequent to the granting of the doctoral degree. For applicants preparing for practice as health service providers, 1 of those 2 years must be a predoctoral internship. Although they recommended elimination of the postdoctoral requirement for licensure, the Council of Representatives did affirm that postdoctoral education and training remains an important aspect of continuing professional development and the credentialing process for professional psychologists, as it is a foundation for practice improvement, advanced competence, and interjurisdictional mobility. The council also supported the further development of competency goals and assessment methods in the professional education and training of psychologists. In anticipation of this new stand by APA, one jurisdiction (i.e., Washington) has eliminated the postdoctoral requirement, and several others are considering a similar change.

The elimination of the postdoctoral year was and remains quite controversial. Proponents of this decision cite difficulties faced by students trying to secure the required experience for licensure, problems finding suitable positions with appropriate supervision, the limited financial remuneration associated with the postdoctoral year, the heavy debt load that students have upon internship completion, the protracted duration of training, and the fact that the requirements for licensure in psychology are more stringent than those in most professions.

Opponents of the elimination of the requirement express concerns that many students who complete their doctoral degrees have not yet achieved certain competencies crucial for licensure, and that further training and supervision are imperative for students to obtain these competencies. They also believe that eliminating the requirement reduces the profession's efforts to protect the public and consumers of psychology. These concerns have arisen, in part, from the belief that many practicum experiences are not providing sufficient training or supervision necessary for the development of the competencies required for independent practice. Of note, in one survey, students

(graduate, interns, postdoctoral residents), trainers (graduate, internship, postdoctoral), and APA members endorsed the value of the postdoctoral requirement, although they did not believe that a formal program should be mandatory. Furthermore, a recent national survey revealed a discrepancy in training directors' views of trainees' readiness to practice independently. Academic training directors reported that trainees are readier for independent practice earlier in the training sequence than internship and postdoctoral training directors reported.

### ***Supply and Demand***

As noted above, it is difficult to be certain about the number of postdoctoral training programs. There was documented evidence of 22 sites in 1960–1962, 46 in 1967, 161 in 1986, 388 in 1993, and 480 sites that had paid positions in 1998. However, there is a relative shortfall in the number of sites and available slots given the number of individuals in predoctoral internship programs. This has resulted in an insufficient number of formalized positions. However, many students choose to complete their postdoctoral experience requirements through supervised work experience rather than via a formal postdoctoral training program.

## **Characteristics of Postdoctoral Training**

### ***Training Emphasis and Sites***

Postdoctoral training programs may emphasize clinical or research training. There are accredited programs that are broad and general in professional psychology as well as those in such specialty areas as clinical child, clinical health, clinical neuropsychology, and rehabilitation psychology. Most APPIC member programs are based in medical schools, university counseling centers, Veterans Affairs Medical Centers, and child settings. There also are positions in industry and government. The setting influences the experiences fellows will gain and the dominant populations with whom they work.

### ***Formal and Informal Postdoctoral Training***

Postdoctoral training may be informal or formal. Informal refers to on-the-job supervised experience, designed primarily to assist the individual in fulfilling

licensure requirements. These positions often entail high service demands and considerable levels of professional autonomy. Conversely, formal postdoctoral training occurs in the context of an organized and structured educational program designed to develop advanced competency and expertise for the professional practice of psychology. Stipends typically are set. These positions are advertised through the *APPIC Directory*, the *APA Monitor*, and the Association for Psychological Science's *APS Observer* as well as on various listservs.

A survey of interns revealed that, in general, they preferred an informal postdoctoral experience. This preference appeared to be based on personal and practical considerations, and such factors often outweigh professional considerations. Such considerations relate to finances, concerns about relocation, dual career demands, family goals, and relationship commitments.

Those who complete formal programs rate these experiences as more valuable than those who participate in informal programs, as these programs bolster their competence in professional practice, clinical research, supervision, and teaching; provide them experiences with particular populations; and enhance their job marketability. A study of individuals in formalized postdoctoral fellowships highlighted that a desire to secure focused training in specific areas and a need to obtain further experience that would increase their marketability were key in deciding to apply for formalized fellowships. Formalized postdoctoral training is essential for certain specialties and is highly desirable in certain geographic regions.

### **Specialty**

For many years, there has been a general consensus that postdoctoral education and training are valuable in terms of specialty practice. A position first evidenced at the Boulder conference, it was solidified at the Stanford, Miami, and Chicago conferences as well as at the National Conference on Implementing Public-Academic Linkages for Clinical Training in Psychology.

Many sites offer training at multiple levels (e.g., practicum, internship, postdoctoral) within a given specialty area, despite the fact that the only specialty programs that can be accredited are at the postdoctoral level. Within each specialty area, there is heterogeneity in the types of postdoctoral training offered, raising questions about core competencies to be achieved

in each specialty area at the postdoctoral level. Individuals who receive postdoctoral training in various specialty and proficiency areas reveal a high degree of satisfaction with their experience and an enhanced sense of competence. Specialty training at the postdoctoral level increases marketability and is mandatory for some specialties.

### **Developmental Perspective**

This phase of professional development is characterized by a focus on negotiating the tasks of individual and professional self-definition. Individuals begin to develop expertise in areas of personal interest; manifest a deepening commitment to the work; experience an enhanced sense of personal efficacy, confidence, and self-acceptance as psychologists; and are perceived by others as competent psychologists.

A postdoctoral training program offers a transition period between being a student and professional employment, and making this transition is a task with which individuals often struggle. Although supervision and training continues, there typically is greater professional autonomy during a postdoctoral training program than there was during the internship year, and thus the experience facilitates transition from dependence to independence. Many postdoctoral programs pay particular attention to assisting their trainees in securing their first professional employment in psychology.

### **Funding**

One major concern for students in making decisions regarding postdoctoral experience relates to funding. There are a broad range of financial arrangements for informal postdoctoral supervised work experience. However, formal postdoctoral positions are typically funded by the institutions in which they are embedded. As of the 2006–2007 training year, the mean salary for individuals in APPIC member postdoctoral training programs was \$35,000/year, with a range from \$15,000 to \$72,000/year. For APA accredited programs, the mean is \$42,800 and the range is \$29,000 to \$70,000/year. For the number of programs and slots to be increased, additional funding streams need to be secured. Limited graduate psychology education funds are available for accredited postdoctoral fellowship programs. APA has made efforts toward passing legislation that would allow graduate medical education

funding through Medicare to support psychology postdoctoral training programs. However, few institutions have been able to secure these funds for their programs.

### Future Directions

Individuals seeking postdoctoral training should define their training objectives, be cognizant of the relevant licensure requirements, and be mindful of the advantages of securing such training in terms of specialization and networking. Young professionals should examine their professional and personal goals to ascertain whether to seek formal or informal postdoctoral training and to determine the extent to which their training will be specialty specific. As jurisdictions become more variable with regard to the postdoctoral requirement, individuals need to determine if they will even need to secure such supervised experience.

It also may behoove the profession to better standardize the postdoctoral training requirements on a national basis. In addition, greater consideration could be given to implementing a matching process for formalized postdoctoral programs akin to that already in place for the neuropsychology postdoctoral programs and for internship programs. Finally, the profession could more effectively convey the value of postdoctoral education and training, particularly that which occurs in formalized programs.

## PREDOCTORAL INTERNSHIPS

---

The predoctoral internship, a vital component of professional psychology education and training, is one of the formative experiences for individuals obtaining doctoral degrees and licenses in psychology. Generally considered the capstone year of doctoral training, it provides students the opportunity to expand upon and integrate their clinical experiences, to be exposed to diverse patient populations, and to experience a variety of perspectives both within and outside of psychology.

This entry begins by providing a historical backdrop of the predoctoral internship experience. The key issues and trends that dominate current thinking regarding internship training, with particular focus on supply and demand imbalance, financial considerations, areas of emphasis, the application process, and the APPIC Match are addressed. The student perspective on the internship experience also is offered.

### History

The American Psychological Association (APA) inaugurated internship training at the Boulder conference in 1949. Conference participants mandated that a 1-year, full-time internship experience would be required for the doctoral degree in applied psychology. Accreditation of predoctoral internship programs through the APA began in 1956, and by the end of 2006 there were 455 APA-accredited programs. The Canadian Psychological Association began accrediting programs in 1984. While the accreditation system has been modified over the years, it has been continuously supported by the profession. However, there have been and remain various perspectives regarding the value and structure of the accreditation process.

In 1968, the Association of Psychology Internship Centers (APIC) was formed as an informal cadre of psychologists invested in training predoctoral interns. In 1992, the organization expanded its mission to include postdoctoral training and was renamed the Association of Psychology Postdoctoral and Internship Centers (APPIC). APPIC, which is committed to enhancing internship and postdoctoral training in professional psychology, establishes minimal standards for quality training programs, develops selection policies and procedures for matching applicants to internship programs, publishes a directory of

programs, facilitates the placement of unmatched applicants, assists with the informal and formal resolution of problems related to internship and postdoctoral training, represents the views of internship and postdoctoral agencies at the North American level, and takes a leadership role in national and multinational psychology conferences. One such conference was the National Conference on Internship Training in Psychology held in Gainesville, Florida, in 1987, the only national meeting devoted exclusively to internship training. Delegates developed a policy statement on internship training and delineated core requirements for the internship experience.

From the 1972–1973 training year through the 1997–1998 year, APPIC coordinated a “uniform notification” system, a process by which internship offers were tendered and positions were accepted based on a specific set of rules. Given the multitude of problems associated with this system, APPIC in 1999 initiated a computer-based internship matching program (the APPIC Match) to facilitate the placement of applicants into available positions.

Psychology typically has emphasized 1-year, full-time internships, although many students with family, financial, or other obligations have great difficulty in completing a full-time training program. While the 2006–2007 *APPIC Directory* lists only 15 2-year, half-time funded internship positions (0.5%), 5% of applicants who responded to a 2005 APPIC survey reported that they would prefer a half-time internship experience. In 2005, a national conference identified the benefits of half-time internship training, obstacles to implementing such training, and potential solutions for overcoming these barriers. A compelling case is being built for developing and promulgating systematic and coherent half-time internship program designs and structures. There are a number of excellent examples of half-time internship models and efforts to ensure the quality of these programs.

### Supply and Demand

In the early to mid 1990s, concerns began to be raised about a potential imbalance between the number of applicants (supply) and the number of available internship positions (demand). This led to a 1997 APPIC-APA sponsored conference on “Supply and Demand: Training and Employment Opportunities in Professional Psychology.” This imbalance has become more pronounced over the last several years,

with a total of 3,210 applicants competing for 2,779 available positions in the 2006 APPIC Match. These figures do not consider those applicants who withdrew from the Match because they were rejected from all sites to which they applied or the fact that some students and programs crafted new funded or unfunded positions after the Match had been completed. Between 2001 and 2005, the number of registered applicants increased by 275 and the number of available positions increased by only 16, suggesting that the growing imbalance reflects an increase in the number of students rather than a reduction in the number of positions.

As the supply–demand imbalance continues to increase, applicants may feel growing pressure to focus more on obtaining a placement than on the quality of the placement itself. Similarly, doctoral faculty may experience pressure to lower their standards for internship to ensure their students' graduation. These phenomena can result in reduced incentives for new and existing internship programs to seek accreditation or APPIC membership, because those programs can easily fill their positions without meeting national standards. It also has increased pressure on students to complete more practicum hours to remain competitive, potentially interfering with their ability to complete other academic and research requirements. Further, students who accept nonaccredited or non-APPIC member internships run the risk of experiencing difficulties related to future licensure or employment.

### Financial Considerations

Financial issues related to internship training need to be considered for students and programs. First, given the supply and demand imbalance, students feel compelled to apply to and interview at an increasing number of sites, which is associated with significant costs in terms of time and money. For the 2006 APPIC Match, applicants reported spending an average of \$1,508 for the entire process. Second, intern applicants are underpaid; of the positions listed in the 2006–2007 *APPIC Directory*, the mean internship salary is \$21,600 for all APPIC-member programs and \$22,700 for all accredited programs. This is despite the fact that a growing number of programs have increased their stipends to \$23,660 consistent with the standard set by Fair Labor Standards Act. Third, there are limited federal funds to support internship training, as only recently have graduate psychology education funds

been accessible. Fourth, there are questions about the cost-effectiveness of programs given the time and resources required to train students and the fact that most agencies are not permitted to bill insurance companies for interns' services.

### Areas of Emphasis

Among the 621 member programs listed in the 2006–2007 *APPIC Directory*, internship training occurs in Veterans Affairs Medical Centers, medical schools, university counseling centers, state hospitals, community mental health centers, child and adolescent psychiatric or pediatric facilities, private general and psychiatric hospitals, military and correctional facilities, psychology departments, private outpatient clinics, and school districts. Some programs include the collaboration of multiple settings into a consortium model, and others involve affiliations between graduate programs and facilities at which internships are offered.

Sites vary in terms of populations served according to age, inpatient versus outpatient, individual and cultural diversity considerations, geographical location, and income of patients. They also differ in treatment modalities emphasized: therapy (individual, couples, family, group), community intervention, consultation and liaison, crisis intervention, brief and long-term therapy, and cognitive rehabilitation. Further, there is variability in the extent to which they provide training in supervision, although with the growing recognition in the field that supervision is a core competency, increasing numbers of sites offer extensive training in this domain. There is marked diversity with regard to specialty areas. Areas of special emphasis that have received considerable attention include those of children and older adults, health care in individuals across the life span, clinical neuropsychology, consultation, and working with individuals with severe and persistent mental illness. Internships also train psychologists for working in settings including managed care; market-driven practice; primary care; and public health, including prevention, public policy, and community action. Many programs highlight teaching in diversity, such as women's issues, religion and spirituality, and multiculturalism. A growing number of programs emphasize training in empirically supported treatments and research.

Recently, it has been argued that the structure of internship programs is not sufficiently responsive to

emerging trends and practice opportunities in the field but is rather overly focused on training individuals for the traditional clinical-provider role. This may contribute to an oversupply of clinical practitioners and a lack of adequate preparation for interns to compete for jobs in new areas of psychological practice.

Despite APA's efforts over the past decade in requiring internship programs to define and articulate their model of training, characteristics of a training program may be better described by the setting and areas of emphasis than by the articulated training model. Similarly, there appears to be a poor relationship between the model of students' doctoral programs and the model represented by students' choices of internship. Clearly, more work is required in this area. Because current training models do not capture differences in training sites, new paradigms are needed to better capture similarities and differences in approaches to training across programs.

### Application Process

There have been multiple changes to the internship application process in recent years. First, the *APPIC Directory* is now online, which allows students to more effectively search for sites that appear to be a good fit for their training interests. Second, instead of each internship site requiring its own unique application, most sites now accept a standardized application, the APPIC Application for Psychology Internships (AAPI). As of this writing, the AAPI includes background and educational information, documentation of supervised practicum experiences, test administration and report writing experience, professional conduct, and essay questions. Five essay questions require applicants to provide an autobiographical statement along with information about theoretical orientation, experience and training with diverse populations, research interests and experiences, and the fit between themselves and the specific site. Third, due to increasing concerns about the inflation of letters of recommendation and the lack of attention in such letters to applicants' limitations and areas of growth, suggestions for more balanced and useful letters have been provided. Programs in Canada have established guidelines for a uniform letter of recommendation that includes information about how the recommender knows the applicant, current professional and personal competencies of the student, areas for personal growth and development, and a summary recommendation.

While requirements vary across sites, a typical internship application packet consists of a cover letter, AAPI, verification of internship readiness from the graduate program, copies of graduate transcripts, and three letters of recommendation. Some sites require work samples (e.g., testing reports). Manuals and articles guide students in preparing strong applications, and research findings shed light on factors associated with positive and negative match outcomes. Applicants are most likely to be matched at a site when the site perceives a good fit between the applicant's goals and clinical experiences and the site's opportunities, when the student has impressive letters of recommendation, and when the person interviews well. Conversely, applicants are less likely to be successfully matched to a site when they have not completed their comprehensives and dissertation proposal defense, have incomplete course work, are not from accredited doctoral programs, and are not viewed as being a good fit.

### The APPIC Match

In 1999, APPIC made a dramatic change to the process in which students were placed into internship positions. Due to the myriad problems associated with the previous telephone-based system of making offers, APPIC implemented a computer-based matching program similar to the one used by medicine and other professions. The Match provides a number of benefits to participants: reduced stress, reduced violations of APPIC policies, better outcomes, elimination of gridlock, and improved experiences for couples. The APPIC Match is administered by National Matching Services, Incorporated (NMS), a Toronto-based company that specializes in the administration of matching programs. The matching process is governed by a set of rules called the "APPIC Match Policies" that are designed to ensure the smooth operation of the process and reduce stress and pressure on applicants.

Applicants typically begin the selection process in the summer or fall by identifying internship programs in which they are interested, usually with the assistance of the *APPIC Directory Online*. Application deadlines typically are between November 1 and December 1, with interviews occurring during December and January. Some programs offer telephone interviews, while others prefer applicants to interview on-site, usually at their own expense.

Upon completion of interviews, each applicant and program submits a "rank order list" (ROL) to NMS by

a predetermined deadline (currently in early February). An applicant's ROL consists of a list of programs in which he or she is interested in the order in which he or she prefers them. Similarly, a program's ROL consists of a ranked list of applicants. Both applicants and programs are encouraged strongly to rank according to their true preferences, without considering other factors (e.g., how others ranked them, competitiveness of a program), as this maximizes their chances of getting the best possible match. Special ranking procedures are available for couples so they can attempt to geographically coordinate their placements.

Results of the Match are provided in a two-step process currently held on a Friday and the following Monday in late February. Match results are considered binding on all parties. On Friday, applicants are told whether or not they matched, but they are not told the specific program to which they matched. Programs are not provided any results on that day. On the following Monday, applicants learn the site at which they matched. Programs receive a list of students to whom they matched. This three-day delay allows unmatched applicants the chance to regroup and prepare to participate in the "APPIC Clearinghouse," a process that facilitates placing unmatched applicants in positions left unfilled by the Match.

### Student Perspective

There has been some attention paid to factors that determine whether or not applicants apply to a particular site. Students appear to apply to sites based on a gut feeling of sense of fit with the program; perception of good fit between personal interests and program's strengths; program's prestige or reputation; amount, quality, and content of the education in terms of supervision and didactic activities; breadth of populations served; areas of special emphasis; and geographic location. They also are drawn to programs in which they perceive a sense of community, respectful treatment of clients and colleagues, and support for authentic interactions. Individuals interested in pursuing academic careers often consider research opportunities at the site. Applicants tend not to apply to sites if they perceive they have a limited fit with the program or location or if there are financial or partner concerns associated with the program. Thus, professional, personal, and practical considerations influence decision making.

During the internship year, interns solidify their professional identities, refine their competencies, and gain entry to the next phase of their careers. Interns experience their training year as a time of personal and professional transitions, "passages," and critical events, and they grapple in a condensed fashion with each of Erikson's psychosocial challenges. They encounter developmental stressors during the year, including adjusting to a new training and clinical environment, developing trusting relationships with supervisors and peers, questioning their competence as psychologists, taking risks to acquire new competencies with a broad array of populations, engaging in self-assessment, and career planning. They participate in myriad self-care activities to assist them in managing these stressors, including seeking support of family and friends, active problem solving, participating in pleasurable activities, and humor.

### Future Directions

Looking to the future, the profession may need to address a number of critical issues. First and foremost, the increasing supply-demand imbalance threatens professional psychologists' ability to effectively train students seeking their doctoral degrees and imposes severe delays and hardships on hundreds of students each year. Although myriad strategies have been proposed to redress the supply-demand imbalance, a systematic or concerted national effort may help ameliorate this growing crisis.

In addition, the profession may benefit from increasing the opportunities for 2-year, half-time internship experiences, enhancing advocacy efforts at the federal and state levels for increased financial support of psychology internship programs (such as the recently established graduate psychology education program), and ensuring that internship programs are appropriately preparing students for the new and emerging practice opportunities in professional psychology.

## PRESCRIPTION PRIVILEGES

---

Prescription privileges refers to the right to prescribe medication. The psychologist prescription privilege (PPP) debate refers to legal and ethical arguments for and against a psychologist prescribing medication. Presently, there are legal avenues by which a psychologist may earn the right to prescribe medication. A psychologist could elect to earn a supplemental degree in such fields as medicine or advanced practice nursing and gain legal authority to prescribe. Extending prescription privilege to psychologists would provide a different and, presumably, less onerous means for a psychologist to gain the right to prescribe. In the United States, granting prescription privileges to psychologists was attempted by various pilot programs in New Mexico, California and, most notably, in the military. Recently, two states, Louisiana and New Mexico, have passed laws to permit additional avenues whereby a psychologist may prescribe medications. As of April 2005, legislatures in 20 states either began studying the impacts of extending PPP or have proposed prescription privilege legislation.

In the United States, only physicians have full prescription privileges. Other professions such as optometry, dentistry, and podiatry are granted limited prescription privileges to prescribe medications that affect the body systems in their area. By the year 2002, approximately 75,000 nonphysicians, including nurse practitioners, midwives, and other clinical specialists had prescription privileges across the United

States. In 38 states, pharmacists had the power to prescribe medications.

Those psychologists in favor of granting prescription privileges to psychologists have been represented by the American Psychological Association (APA), an organization whose membership is largely composed of clinicians and independent practitioners. Those opposed to PPP represent two separate camps: those within the psychology profession and those outside of the psychology profession, many of whom are members of the medical establishment.

Psychologists standing in opposition to PPP have been represented by the American Association of Applied and Preventive Psychology (AAAPP), an organization created by psychologists opposing the proliferation of states authorizing PPP, and the Society for a Science of Clinical Psychology. Several physician groups, including the American Psychiatric Association and the American Medical Association (AMA), have also opposed allowing psychologists to have specific training permitting them to prescribe psychotropic medication.

### **The American Psychological Association's Proposal**

Currently, the APA proposes that psychologists earn the right to prescribe medication that directly affects individuals' mental health needs. Both Louisiana and New Mexico have passed legislation that has closely mirrored the APA's recommendations. The APA guidelines indicate that only those who hold a doctorate in psychology and have five years of experience in the health-care industry should earn prescription privileges. Once the doctoral degree has been earned, a psychologist should take 450 hours of training in five areas: neuroscience, clinical psychotherapeutics, physical and laboratory assessment, physiology and pathophysiology, and clinical and research pharmacology and psychopharmacology. Following the didactic portion of the training, psychologists complete a 400-hour practicum, including 2 hours of weekly supervision, and treat at least 100 patients with mental disorders. The practicum would be followed by a certification examination that would allow for a 2-year probationary period during which the psychologist would be supervised by a physician. Following these 2 years of supervised practice, the psychologist would become eligible to earn a license to prescribe medication.

## **History of Psychologist Prescription Privilege**

### ***The Military***

In 1989, the department of defense (DOD) launched a program to train psychologists in the military to prescribe medication. The program's base included 1 year of didactic training followed by 1 year of clinical training. Ten individuals went through the training. As of 2003, 7 of the psychologists who had initially been trained were continuing to actively prescribe medication, while the other 3 were working on advocacy or attending medical school. The DOD program, which cost over \$6 million, was stopped at the end of 1996. Proponents of the program claimed that psychologists had shown their ability to safely prescribe medications to patients and were able to provide both psychopharmacological and psychotherapeutic services together. Opponents felt that the program was expensive, that the psychologists were overly reliant on physicians, and that the psychologists were only able to prescribe to a restricted group of the active enlisted military.

### ***New Mexico***

In March of 2002, the state of New Mexico passed legislation allowing properly trained psychologists the right to prescribe medication on a limited basis. The regulations came into effect in January of 2005. The law closely followed the recommendations of the APA in terms of training and accreditation. The psychologists' training includes an 80-hour practicum in clinical assessment and pathophysiology. After a psychologist earns prescription privilege, and following a 2-year probationary period during which a psychologist works with a physician, a psychologist can apply to prescribe medication independently. However, when prescribing, a psychologist must maintain a close collaborative relationship with a patient's primary physician. This collaboration is designed to ensure that an individual is receiving regular medical physical exams, to ensure that there are no adverse reactions to the medication, and to provide a safeguard to prevent the prescription of medications that may have dangerous interactions with one another. To maintain a prescription license, a prescribing psychologist must receive 20 additional hours of training each year. A prescribing psychologist is allowed to prescribe medication and order requisite laboratory tests only for the treatment of mental

disorders. The licensing board charged with allowing psychologists the right to prescribe psychotropic medications is run by physicians. Many psychologists argue that the physicians are too conservative and may be predisposed against allowing PPP. The PPP proponents claim that this regulation limits many qualified psychologists from earning the prescription privilege.

### ***Louisiana's Medical Psychologists***

In May of 2004, Louisiana became the second state to allow psychologists to prescribe psychotropic medications. The Louisiana law stipulates that a psychologist must complete 2 years of postdoctoral training by earning a master's degree in clinical psychopharmacology from a regionally accredited institution. He or she must then pass a national examination. The psychologist is then allowed to prescribe medication provided he or she works in conjunction with the patient's primary physician. The law permits medical psychologists to prescribe medication only related to nervous and mental health disorders.

Louisiana's law is slightly different in that the board that oversees prescribing psychologists is the Louisiana state board of examiners of psychologists, a nonphysician board. Also, the Louisiana law does not require a 2-year probationary period during which a psychologist must work closely with a physician's oversight when prescribing medication.

## **The Psychologist Prescription Privilege Debate**

The issue of extending prescription privileges to psychologists (PPP) has become possibly the most contentious debated proposal advanced in the field's recent history. Few topics have a more polarizing effect. This rancor is likely a direct result of the debate's high stakes. The contest over prescription privileges has moved beyond the proposals and hypothetical ponderings first offered 18 years ago in the pages of professional and academic journals. In recent years, the issue has entered the realm of state legislative subcommittees, and in several states the issue has become a bill put up for a full state-level legislative vote.

### ***The Debate Among Psychologists***

The competing views of professional psychologists regarding the extension of prescription privileges to

psychologists were not adequately resolved before the question became a matter of public policy. The resulting high-stakes legislative debate has fueled a growing schism in the already fractionated field of professional psychology. Studies performed at the end of the 1990s found that nearly twice as many psychologists opposed PPP as favored it. However, as the movement has gained momentum, a greater percentage of psychologists have given at least tacit assent to the idea of advancing PPP. However, many argue that the interdisciplinary schisms within the field of psychology are sufficient to indicate that PPP should not be advanced. This public controversy has generated discussion rather than problem solving, and the opposing points of view have confused legislators and stalled or stopped several PPP bills from passage. Despite the confusion and controversy, the debate is more alive now than ever before. An increasing number of states are introducing bills that, if passed, would extend prescription privileges to psychologists. As these hotly contested bills are presented to states' legislative bodies for debate, psychologists and the professional organizations formed to advance their views and positions are submitting position statements, legal briefs, and sworn testimony to promote their respective positions for and against PPP.

## **The Pros and Cons of PPP**

A comprehensive review of the various positions articulated by psychologists for and against extending PPP reveals the following five central and recurrent themes around which the arguments are framed:

1. Would prescribing psychologists fill a real and pressing societal need?
2. Would prescribing psychologists provide a less expensive alternative to current prescribing health-care professionals?
3. Would the training of professional psychologists be adversely affected by additional course work necessary to develop the knowledge base and skills to competently prescribe?
4. Would prescribing psychologists provide greater continuity of care and a more comprehensive service than conventional collaborative models?
5. Does an ample precedent for successful PPP exist?

## ***Societal Need***

Regarding the issue of societal need for PPP, the position advanced by the APA claims that an insufficient number of psychiatrists are available to adequately offer a complete array of mental health services, including the prescription of psychoactive medications. As a result, traditionally underserved populations (e.g., women, children, the elderly, inner city residents, and members of rural communities) are being deprived of quality mental health assessment and intervention.

The APA offers statistics suggesting that the majority of visits to primary care physicians are made by persons for whom no diagnosis of physical illness can be made and whose complaints result from psychological issues. The argument follows that psychologists are more familiar with mental disorders than are nonpsychiatrist physicians (general practitioners) who are currently prescribing approximately two thirds of all psychotropic medications in the United States.

General practice medical doctors typically receive less than 2 months of training in mental health and psychiatry. The APA argues that, with the appropriate supplemental training in physiology, chemistry, biology, and psychopharmacology, psychologists would be adequately equipped to serve the psychopharmacologic needs of people suffering from mental disorders. Psychologists would be able to offer the unique blend of psychological and psychopharmacological interventions that have previously fallen only into the realm of psychiatry.

The AAAPP position simply holds that the need to prescribe is filled by a sufficient number of physicians, nurse practitioners, and other members of the medical community. In fact, they argue that there is a surplus of physicians. Issues of poor distribution of psychopharmacological health care to reach traditionally underserved populations would best be addressed through subsidies and incentive programs. Many of the nonpsychologists who oppose the extension of PPP claim that psychologists who have specific training in psychopharmacology may harm their patients due to their narrow training. They also claim that physicians would be required to provide intensive oversight to psychologists.

## ***Expense***

The APA believes that psychologists with prescriptive privilege can provide medical mental health care more cost effectively than can psychiatrists,

psychologists working in conjunction with physicians, or other combinations of mental health service provision. Frequently, a consumer of mental health care service will need to see a physician or psychiatrist for medication and a psychologist for psychotherapy and other behavioral health interventions, including case management and diagnosis. Psychologists with prescription privilege become valuable because they independently can serve the function of both general practice physicians and mental health treatment providers. These combined services result in fewer office visits for the consumer and, thus, less expense. Secondly, hourly rates for psychological services are typically significantly lower than costs for psychiatric or general practitioner services.

Proponents of PPP also dispute the claim that psychologists interested in prescription authority need only enter training programs for other professions who are able to prescribe, such as those for nurse practitioners or physician assistants. A training program that is focused only on psychotropic medication will provide only the necessary expertise for a psychologist who chooses to prescribe psychotropic medication. The time and expense involved in becoming a nurse practitioner, a physician assistant, a dentist, or a physician is prohibitive and results in an extraneous skill set for a psychologist. This savings in training would result in lower costs for both psychologists and for the general public.

The AAAPP argues that any cost savings a psychologist may have offered would be eliminated by the costs involved in training, regulating, and supervising psychologists with prescription privilege. For example, the military's attempt at training psychologists was exorbitantly expensive and cost prohibitive for civilian psychologists. These supplemental expenses would, as the AAAPP asserts, eventually be passed on to consumers.

## ***Training***

At the heart of the training debate is the question as to whether the APA's recommended education for psychologists interested in obtaining PPP will sufficiently prepare psychologists and safeguard the community from unqualified personnel. The current recommendations advanced by the APA include 2 years of postdoctoral training, a 400-hour supervised practicum specifically addressing psychoactive medication management, and 2 years of subsequent

clinical supervision by a physician. By contrast, nurse practitioners and physician assistants typically are required to complete 600 total hours of practicum experience, after which these professionals become license eligible. For physician assistants and nurse practitioners, these hours include nearly all training involved with patient care, not only medication management. Thus, the APA contends that the postdoctoral training of psychologists provides ample exposure to and practice with prescribing psychotropic medications. Moreover, because this training is postdoctoral and voluntary, it would not necessarily infringe upon the traditional training practices of professional psychology programs.

Many in the APA would argue that psychologists already represent the highest standard of nonmedical mental health care. These professionals offer expertise in the diagnosis and treatment of mental health disorders. This level of expertise far exceeds the experience of most general practice physicians and certainly that of physician assistants and nurse practitioners. A psychologist with supplemental training in prescribing psychoactive medication would offer a unique variety of interventions and a singularly proficient view of patient care.

Psychologist opponents to PPP articulate concerns that the fundamental focus of doctoral level psychological training programs would be altered substantially. These programs, as posited, would be required to focus much more intensely on the biological bases of behavior and on psychopharmacology. Additionally, undergraduate coursework in biology, chemistry, and other sciences may be additional requirements. If training programs focus more heavily on psychopharmacological interventions, nonmedical interventions and their subsequent benefits may be deemphasized in psychologists' practice. These concerns also extend to the entire enterprise of training psychologists. Professional psychology is currently a highly fractionated and diverse field. To properly train a highly qualified professional psychologist, a broad regimen must be undertaken. These training protocols require a psychologist to demonstrate competence across a broad array of theoretical orientations, clinical perspectives, and subdisciplines, including development, cognitive science, behavioral science, and counseling.

Those concerned by the introduction of PPP fear an overemphasis on psychopharmacological interventions, reliance on reductionistic solutions involving only medication, and a departure from the traditional province of

psychology, which may result in an underemphasis on areas where psychologists have traditionally excelled—in assessment, psychotherapy, and behavioral intervention. Further, PPP opponents are concerned that an increased emphasis on PPP would result in psychology following an increasingly medical model that is focused on extrinsic, individual pathology.

The American Medical Association (AMA) is also opposed to PPP on the basis of training. They assert that prescribing psychologists would require an unreasonably high level of ongoing supervision. This supervision would not only increase costs, but failure to provide this level of supervision would increase the risks to the general public. They argue that all medications affect the entire organism and that a training program focused only on psychotropic medications fails to appropriately address the complexity of the human system.

### ***Continuity of Care***

Those who support PPP argue that obligatory collaboration between various mental health care providers, by definition, interferes with continuity. When multiple care providers are involved in a patient's treatment, it fractionates care. A patient who elects to see a psychologist for psychotherapeutic and assessment services is required to see an entirely different individual for prescription and monitoring the effectiveness of medication. This is currently true under existing laws governing psychological practice in 48 of the 50 states. Additionally, in many cases, healthcare providers who are prescribing will conduct their own, independent assessment. Assessment techniques practiced by nonpsychologist practitioners often fail to meet the psychometric rigor and best practice standards of psychologists. In this way, multiple care providers are more likely to duplicate assessment services. This duplication not only generates unnecessary expense but also occasionally contributes to disagreements in diagnosis and treatment recommendations.

Disagreements in diagnosis and treatment recommendations stem not only from differences in philosophy, professional orientation, and training experiences but also from simple communication breakdowns. Discontinuity of care increases the likelihood of communication breakdowns. For example, an individual consumer of mental health care may become confused about which mental healthcare provider received

various pertinent details of case history. As a result, he or she may neglect to adequately supply a comprehensive account to one or both caregivers. This discontinuous approach often leads to incomplete assessment and treatment protocols, because necessary information is not fully gathered and not fully shared between care providers. Only in rare cases can caregivers sit down, compare notes, and discover omissions and inconsistencies. The risks involved in potential communication breakdowns between busy professionals put the client in danger of substandard care. These dangers may include conflicting diagnoses, incompatible treatment regimens, different methods of measuring outcomes, and divergent notions of treatment success.

Those opposed to PPP argue that collaboration is a standard aspect of both psychiatric and psychological practice. Representatives of these professions are accustomed to embracing other viewpoints and are trained in multidisciplinary treatment approaches. Patients benefit from the unique contribution supplied by practitioners versed in an array of specialties with varying areas of expertise. A multidisciplinary treatment approach is helpful, because specialists bring their own vantage to understanding psychopathology and subsequent treatment. Placing too many treatment options in one practitioner's arsenal may result in a narrowing of treatment protocols, thus failing to incorporate multiple viewpoints and possibly neglecting viable treatment options. In sum, the opponents of PPP suggest that the dangers articulated with the requirements of collaboration are overstated and overshadow the risks associated with nonphysicians prescribing medication.

### ***Precedent***

The APA position points to past and current instances of psychologists safely and effectively providing psychotropic medications to their patients. Such instances include the military's use of psychologists with prescribing authority and time-limited experimental programs executed in New Mexico and California. Further, the APA states that other nonphysician service providers have safely been extended prescription privilege.

During the mid-1970s, the state of California launched a program to extend prescription privileges to many nonphysician mental health providers. These individuals received extensive training in prescribing medications, but they were never legally extended the

privilege of prescribing medications. In the Indian Health Sciences Center in Santa Fe, New Mexico, a project that allowed one psychologist to prescribe a limited number of medications was also deemed to be effective during 1988–1989. There were further attempts to extend the prescription privileges to other nonpsychiatrist service providers that many argue were successful in both scope and safety. The APA also argues that reviews of the performance of psychologists in the DOD have indicated that psychologists have been able to prescribe psychopharmacological interventions safely. Through this program, called the Psychopharmacology Demonstration Project (PDP), 10 psychologists were trained to prescribe medications. Two independent reviews of the military's prescribing psychologists indicate that the psychologists demonstrated high levels of competence and offered excellent care when prescribing psychopharmacological medications. Further, proponents argue that these 10 psychologists have lessened the workload on physicians, have shortened wait times for mental health services and follow up, and have extended care to a broader constituency.

Those opposed to PPP state that previous pilot projects have been limited in scope and disproportionately expensive, and they have required psychologists to be closely monitored by physicians. For example, they state that the DOD project cost \$6 million dollar while training only 10 psychologists. Moreover, they argue that the psychologists needed to be so highly supervised by physicians that their independence was put into question. Finally, opponents argue that the military's psychologists were restricted to treating relatively uncomplicated cases. In the Santa Fe Indian Health Sciences Project, only one psychologist was extended prescription privilege, indicating a limited precedent. The AMA has argued that previous experiences with PPP have required physicians to undertake an undue financial and time burden in supervising relatively naïve psychologists. Thus, the opponents have stated that the expense and training obstacles have proved too onerous and have not resulted in sufficient benefit for the general public.

### **Future Directions**

The prescription privilege debate cuts across many intellectual and proprietary boundaries. Within the field of psychology, the debate focuses on the quality of service provided by psychologists and whether extending

PPP would improve or diminish psychologists' abilities to provide the highest quality mental health care. The discussion between members of the psychological community and those outside of the psychological community has focused on the effects of increasing the number of psychopharmacological prescribers and whether such expansion would provide better or worse service to the general public. As state psychological associations continue to propose legislation, and as physician and psychological groups oppose this legislation in various states, the debate will certainly continue for years to come.

## PROFESSIONAL ASSOCIATIONS, COUNSELING

---

The American Counseling Association (ACA) is the primary organization to which professional counselors belong. The association includes 19 divisions, 56 branches, and 5 professional partners (i.e., affiliated organizations). Approximately 45,000 counselors from the United States and 50 other countries belong to ACA. The headquarters are in Alexandria, Virginia. According to the association's bylaws, their mission is to "enhance quality of life in society by promoting the development of professional counselors, advancing the counseling profession, and using the profession and practice of counseling to promote respect for human dignity and diversity." Members of the association actively advocate for social justice as well as the promotion of the profession.

### History

Although the organization was incorporated in 1952, its history can be traced to the turn of the 20th century, when the association's first division, the National Vocational Guidance Association (NVGA), was established independently in 1913. Eleven years later, in 1924, the American College Personnel Association (ACPA) was founded. The Student Personnel Association for Teacher Education (SPATE) was formed in 1931. The National Association of Guidance and Counselor Trainers (NAGCT) originated in 1940.

Discussion of unifying these four groups was introduced in 1949 at a meeting of the Council of Guidance and Personnel Associations. Proponents supported the notion of "one national voice speaking for the guidance and personnel profession" (Simmons, 2002, p. 8). In response, the members of these four existing organizations established the American Personnel and Guidance Association (APGA) in 1952. The annual dues were \$6.00. The offices were leased from the American Psychological Association (APA), and many of the original members and leaders were psychologists. In fact, Donald Super, a psychologist who viewed the fledgling organization as an interest group, became the second president.

Despite Super's perception of APGA as an interest group, the association prevailed and flourished, and each of the original divisions contributed a cornerstone to its diverse areas of identity and philosophy. For example, facilitation of career development remains a hallmark of professional counseling (NVGA's influence). The notion of development extends across the life span, rather than remaining focused on childhood (ACPA's influence). Additionally, counselors have actively participated in various educational enterprises. Counselors have championed ethical practice, unconditional positive regard, equality, advocacy, and human rights (SPATE's influence). Founding members also recognized the importance of preparation for counselors, training standards, theory-based approaches to counseling, supervision, continuing education, and research (NAGCT's influence).

As the subgroups' identities evolved, their names were changed to the National Career Development Association (NCDA), the Counseling Association of Humanistic Education and Development (C-AHEAD), and the Association for Counselor Education and Supervision (ACES). ACPA disaffiliated in 1992. Other divisions were chartered as the organization grew and responded to the needs of its members and society.

By the 1970s, members of APGA recognized the importance of licensure, certification, and accreditation. With the development of these three areas of credentialing emerged standardization of training procedures, identification of minimum qualifications for practice of counseling, and a stronger professional identity. The first licensure law was enacted in 1976 in Virginia. The Council for the Accreditation of Counseling and Related Educational Programs (CACREP) was established in 1981, and the National Board for Certified Counselors (NBCC) was formed in 1982. These three separate but integrally related entities reflect consistency among standards for counselor education programs, licensure requirements, and certification criteria.

By 1987 APGA had grown to 57,000 members, and it became clear that the association had exceeded Super's notion of an interest group. Evolution of the umbrella organization and the addition of divisions during the first 30 years necessitated a change in the association's name. APGA reflected the emphases on students and guidance; it did not capture the essential philosophical underpinning of development or reflect the practice of counseling. Thus, in 1983, the members voted to change the name from APGA to the American Association for Counseling and Development

(AACD). Although this name reflected the philosophy and practice of the association's members, consumers did not easily understand it. Thus, in 1992, members selected the current name, American Counseling Association (ACA).

The early presence of three divisions reflected essential values and emphases among members of ACA. A forerunner of the Counseling Association of Humanistic Education and Development (C-AHEAD) was among the four founding divisions. The Association for Multicultural Counseling and Development (AMCD) was chartered in 1972. The Association for Spiritual, Ethical, and Religious Values in Counseling (ASERVIC) followed in 1974. In 1996 the Association for Gay, Lesbian, and Bisexual Issues in Counseling (AGLBIC) was founded. Counselors for Social Justice (CSJ) received its charter in 2004. The sustained presence of these divisions has demonstrated (a) a consistent commitment to all members and all clients, regardless of their culture; (b) a recognition of the importance of spirituality in counseling as well as development; and (c) a devotion to humanistic principles as applied to human development and potential.

## Partners

In addition to divisions and state branches, ACA has professional partnerships with five affiliates that operate with separate boards of directors.

### *ACA Insurance Trust*

Through the insurance trust, ACA members purchase a variety of insurance packages. The professional liability insurance provides a program in response to the unique needs of professional counselors and counselor supervisors, regardless of their work settings. Policyholders also have access to legal advice.

### *The American Counseling Association Foundation*

The foundation was formed to provide a mechanism for supporting counselors in training, recognizing excellence among ACA members, and publishing excellent materials. The foundation has responded to needs of children through the Growing Happy and Confident Kids program. Additionally, the foundation assists counselors adversely affected by natural disasters through the Counselors Care Fund.

### **The Council for Accreditation of Counseling and Related Educational Programs**

The Council for Accreditation of Counseling and Related Educational Programs (CACREP), mentioned previously, was created to provide standards and procedures for accrediting counselor education master's degree and doctoral programs. A separate board governs CACREP; however, there is a strong affiliation among ACA, CACREP, and NBCC in order to maintain consistent training and certification standards that meet appropriate levels of rigor.

### **National Board for Certified Counselors**

NBCC was formed in 1982 to provide a voluntary credential for professional counselors. Requirements for certification parallel those established by CACREP. Additionally, NBCC monitors specialization credentials such as national certified school counselor and certified clinical mental health counselor. NBCC has developed a variety of examinations that are used by counselor licensure boards (e.g., the National Counselor Examination for Licensure and Certification) and counselor education programs (e.g., the Counselor Preparation Comprehensive Examination). Its Web site contains an array of materials such as *What to Expect as a Client*.

### **Chi Sigma Iota**

Chi Sigma Iota (CSI), which was founded in 1985, is the official international honor society of the counseling profession. The society's mission is to promote scholarship, research, professionalism, leadership, and excellence in all aspects of counseling. Additionally, CSI leaders endorse the importance of CACREP accreditation. CSI includes at least 277 chapters and nearly 12,000 active members, which include counselors in training, professional counselors in a range of practices, and counselor educators. An essential requirement of membership is a clear identification with the profession of counseling, evidenced by counselor education as one's highest or terminal degree.

## **Publications**

The *Journal of Counseling and Development* (JCD) is the flagship journal; its history of title changes (six) reflects the development of the counseling profession.

For example, the original title was *The National Vocational Guidance Bulletin*, which was first published in 1921. The title was changed to *Personnel and Guidance Journal* in 1952 to parallel the formation of APGA. *Counseling Today* is the primary newsletter; it was originally called *Guidepost*. Divisions and branches also publish journals and newsletters.

Additionally a variety of books and other materials are published by ACA. Resources for counselors and counselors in training as well as clients are available on the association's Web site. One practical electronic document is the *Layperson's Guide to Counselor Ethics: What You Should Know About the Ethical Practice of Professional Counseling*.

ACA, several of its divisions, and NBCC have published codes of ethics and standards of practice. These documents are available for review on the various associations' Web sites.

## **Organizational Structure**

The organizational structure of ACA is not unlike that of many other professional groups. Subgroups of the association, known as divisions, are numerous and diverse. As special focus or interest groups, divisions vary in size and mission. State groups, known as branches, of ACA also have state divisions. Additionally, ACA has regional groupings of state branches and divisions as intermediate-level groupings. Representatives of the various divisions and regional groups, coupled with elected and appointed associational officers, compose the ACA Executive Council, the policy-making body of the ACA.

A significant revision in the ACA affiliation framework occurred in the 1990s. Prior to that time, one could be a member of an ACA division only if one were a member of the larger association. However, amid a variety of internal pressures and financial circumstances, the ACA Executive Council determined that a change was needed in the affiliation framework. Beginning in 1998, ACA divisions were allowed to determine whether one could participate in divisional membership without associational membership in the ACA. The previous model was sometimes described as a spoked wheel with strength stemming from the interrelationship between the hub and the various spokes of the wheel. The newer model emphasized the strength of the various spokes of the wheel. Some divisions retained the original affiliation framework, requiring associational membership for divisional

membership (e.g., Association for Counselor Education and Supervision), while others adopted the newer framework (e.g., American Mental Health Counselors Association).

Elements of fragmentation within ACA were obvious during the final decade of the 20th century. Thomas Sweeney noted a specific example in his Article "Accreditation, Credentialing, Professionalization: The Role of Specialties" (p. 123): An invited speaker addressing a group of ACA leaders queried, "Is this a group of groups or a group of the whole?" This statement was context for the speaker's next observation that "if the ACA is a group of groups, then the membership can expect to be ineffective in influencing external groups." However, he further noted that as a single discipline, "counseling could become a core healthcare provider through an amendment to the Public Health Services Act of 1973 similar to what social work, psychology, and marriage and family therapy had done." In this regard, the future of the ACA, while hopeful, remains precariously linked to whether it retains a centralized identity as a group of counselors or a fragmented identity as an amalgam of specialized practitioners and interest groups.

## PROFESSIONAL DEGREES

---

If individuals are interested in a career in counseling or psychology, there are various degrees they can pursue. These fields are very diverse and offer a number of opportunities for those who wish to obtain a master's or doctoral degree.

### Master's Degree

There are many different master's level programs that train students in basic counseling skills. These programs focus on areas such as community counseling, clinical counseling, couples and family therapy, addictions counseling, and vocational counseling. Programs will offer either a master of arts (M.A.) or master of science degree (M.S.). An individual may also obtain a master's degree in social work (M.S.W.). Generally, completion of a master's program in counseling, psychology, or social work requires 2 to 3 years of full-time coursework and a supervised internship.

Licensure varies from state to state for master's level clinicians, but, generally speaking, after completion of a master's program from an accredited university, a candidate may apply for licensure after 1 to 3 years of postgraduate experience supervised by a licensed clinician and after successful completion of the state licensure exam. With a master's degree in counseling or psychology, one can obtain one of two licenses in most states: licensed marriage and family

therapist (LMFT) or licensed professional counselor (LPC). If an individual possesses a master's degree in social work, he or she may obtain licensure as a licensed clinical social worker (LCSW).

Individuals who obtain a master's level degree in the discipline of social work or psychology work in a variety of settings, including community mental health agencies, guidance counseling centers, residential treatment facilities, and drug and alcohol treatment facilities and hospitals, to name a few.

### Doctoral Degree

There are also a variety of doctoral programs in counseling and psychology, some of which can be started after an individual receives a bachelor's degree and others that require that a master's degree be obtained first. Applied psychology doctoral programs include school psychology, counseling psychology, clinical psychology, and industrial-organizational psychology. In all 50 states, the doctorate is the entry level degree for licensed psychologists. Only individuals who have obtained a doctoral degree in professional psychology (clinical, counseling, school, or industrial-organizational) and met a variety of requirements for licensure may call themselves "psychologists." This title is protected and regulated by state licensing boards. The reasoning for such regulation is to protect the public from individuals who are not competently trained to treat individuals with psychological issues.

Most school psychology degrees are offered by an education department within a university, and candidates earn either a doctor of philosophy (Ph.D.) or doctor of education (Ed.D.) degree. School psychologists are specialists in the assessment and treatment of learning and behavior problems of children and young adults. While school psychologists are most commonly employed by school systems, they can also be found working in hospitals, universities, community mental health centers, and private practices. In some jurisdictions, it is possible for individuals to practice as a school psychologist without a doctoral degree. These individuals have earned an educational specialist degree (Ed.S.) and they can be called a school psychologist only while working in a school setting.

Programs in clinical and counseling psychology are offered through departments of education or psychology within a university. The most common degree for these programs is the Ph.D. However, the doctor of psychology degree (Psy.D.) is becoming more

common. Historically, the major distinction between Psy.D. and Ph.D. programs is that the Psy.D. programs focus more on the development of clinical skills than on research skills. Ph.D. programs focus on training clinicians, but they also have a much greater emphasis on the development of research skills as well. While these distinctions between Ph.D. and Psy.D. programs in clinical and counseling psychology generally remain, there is variability in the amount of emphasis a program places on the science and practice of psychology within each degree. There currently are Psy.D. programs that require their candidates to complete a research-based dissertation, and there are Ph.D. programs that permit their candidates to complete clinical case studies in lieu of a dissertation.

Clinical psychology programs educate students on mental health assessment and treatment. Historically, clinical psychologists emphasized the assessment and treatment of individuals with chronic psychiatric conditions. While some clinical psychologists still specialize in working with individuals who have severe psychopathology, others have specialized in helping less impaired individuals deal with life crises and stages. Clinical psychologists work in a variety of settings, including academia, private practice, mental health centers, and hospitals.

Counseling psychology programs tend to emphasize training in psychotherapy and research methods. Counseling psychologists generally work with persons suffering from adjustment issues rather than severe psychopathology. These psychologists are often employed in academia, college counseling centers, community mental health centers, hospitals, and private practice.

Individuals who get degrees in clinical, counseling, or school psychology may then enter a subspecialty in psychology. Some common subspecialties include forensic psychology, health psychology, and neuropsychology.

Forensic psychologists work in a variety of settings as well. These individuals function as clinicians in corrections facilities, work as consultants to trial lawyers, serve as expert witnesses in jury trials, and formulate public policy regarding psychology and the law. Some forensic psychologists have a juris doctor degree (J.D.) as well as a degree in clinical or counseling psychology. There are some programs in the United States that offer concurrent programs, so that the individual can earn both degrees at the same time.

Health psychologists have specialized training in how psychological variables impact health promotion and disease prevention. These individuals are interested in how psychology contributes to the promotion and maintenance of healthy living and to the prevention and treatment of illness. Health psychologists design programs for individuals who wish to stop smoking, lose weight, decrease stress, or maintain physical fitness. These persons are employed by rehabilitation centers, public health centers, academia, hospitals, and private practice. Individuals who function as health psychologists who focus on the treatment of children are called pediatric psychologists.

Neuropsychologists have specialized training in neurology and psychology. Their practice emphasizes how brain disorders and trauma may be manifested in a client's behavior, personality, and cognitive functioning. Neuropsychologists have developed various specialized assessment instruments that are intended to better isolate the likely region of brain dysfunction or differentiate between types of functional impairments that have resulted from brain impairments.

Finally, industrial-organizational psychologists, or I/O psychologists, are interested in the relationship between individuals and their work environments. These psychologists might work to increase workplace productivity while improving quality of life for the worker. Frequently, they play a role in personnel selection. I/O psychologists are employed by companies, businesses, government agencies, and academic settings.

Individuals can also obtain mental health doctoral degrees in fields that are outside of psychology. Two such fields are social work and counselor education. The Ph.D. is the most common degree for a doctorate in social work. Social work programs tend to take a

broader, systematic perspective in helping individuals deal with emotional, health, and adjustment issues. These individuals are trained to help clients identify and qualify for various types of assistance. The entry level degree for social work is the M.S.W., so most individuals seeking a Ph.D. in social work are doing so because they want to work in an academic environment.

The same is true for individuals who obtain a doctorate in counselor education. Counselor educators can become licensed as professional counselors and work in a variety of settings (hospitals, mental health clinics, private practice) with a variety of clients (children, adolescents, couples, and families). Counselor educators can become licensed as LPC. Since the entry level degree for the LPC license is the master's degree, most individuals seeking a Ph.D. in counselor education desire to work in an academic environment where they will specialize in training students seeking the MA degrees.

## QUALITATIVE METHODOLOGIES

---

Qualitative research may be broadly said to be research in which data in the form of words are collected and examined thematically. In other words, what is of interest to the researcher is an exploration, in a natural setting, of the meanings people bring to the qualities, nature, or essence of a phenomenon. The aim of qualitative research is to understand the meaning of human action and to explore and tell the human story. *Qualitative research* is a broad term that encompasses genres such as ethnography, case study, narrative inquiry, phenomenology, grounded theory, life history, oral history, biography, and auto-ethnography.

This entry briefly describes the background of qualitative research; five of the most prominent methodologies (grounded theory, phenomenology, ethnography, case study, narrative inquiry); how to collect data through the use of interviews, observations, and artifacts, data analysis; methods to enhance trustworthiness (a qualitative term for validity and reliability); and possible future directions of qualitative research.

### Background

While qualitative research has been around for some time (since the late 1800s in the United States; e.g. Chicago school sociology, 1892), it has been held in varying levels of respect and acceptance throughout the history of research. Over the last quarter of a century, qualitative research has seen a new level of acceptance in academia. At the same time, ironically, government funded research has touted the so-called

gold standard of experimental research, which has relegated government-funded qualitative research to mere window dressing for randomized experimental designs. The intersection of the tension between government research funding standards and current levels of interest in qualitative research as seen in the increase of qualitative journal articles, conferences, courses, textbooks, and dissertations is the point at which any qualitative researcher is situated today.

## Qualitative Methodologies

### *Grounded Theory*

Grounded theory (GT) is a type of qualitative research in which the primary purpose is to develop a theory based on data. GT is an approach that involves induction, deduction, and verification, although the primary focus is on induction. The term *grounded theory* refers to both the method of data investigation and the analysis as well as the final product of the research. Grounded theory consists of a set of analytic guidelines that allow researchers to inductively build theories. Data collection and analysis occur simultaneously. The process begins with initial data collection typically through unstructured interviews in the field. Data analysis begins by sorting the data into categories that can comprise events, instances, or happenings. The researcher then goes back into the field to collect more data in an attempt to verify or discredit emerging findings. Analysis continues as comparisons between the data are made and the emerging categories are tested and revised. This is referred to as the *constant comparative method*. Data collection and

analysis continue until saturation is reached. *Saturation* is the theoretical term for the moment when it seems no new data need to be collected due to repetition or redundancy in the data.

The data analysis portion of grounded theory consists of three types of coding: open, axial, and selective. When coding data, the researcher breaks field notes or interview transcripts into meaningful chunks or clusters. Each cluster is assigned a code, which is a word or phrase that encapsulates the meaning of the cluster. The clusters could be words, phrases, sentences, or paragraphs. This first phase of coding in a GT study is called *open coding*. It can be thought of as the first pass at creating categories. The researcher then identifies properties of the categories. Open coding is followed by a deeper level of coding called *axial coding*. When conducting axial coding, the researcher looks for new ways to categorize clusters of information. The researcher identifies a central phenomenon, explores occurrences, emotions, or beliefs that influence the phenomenon, and examines the results of the phenomenon. The final phase of coding in GT is *selective coding*. In selective coding, a “story line” is identified that integrates the codes found in axial coding. This story line becomes, in essence, the grounded theory.

While grounded theory refers to the iterative methods of data collection and analysis, it also describes the result, a social theory. The theory, or set of hypotheses, developed about the central phenomenon being studied is based completely in the data, in that all attempts are made to avoid using other theoretical ideas or notions to inform the analysis. The theory is “grounded” in the data, hence, grounded theory. Grounded theory is typically presented with five components: a central phenomenon, causal conditions, strategies, conditions and context, and consequences.

### Phenomenology

The focus of a phenomenological study is to explore the meaning of lived experiences. *Lived experiences* is a term that emphasizes the different and individual lives humans lead. The goal of a phenomenological study is to search for, understand, and explain the essential structure or essence of the phenomenon in question. The experiences are reduced to a description of what all the participants in the study experience.

Phenomenologists tend to use unstructured interviews as their main source of data. The first step in data analysis is to bracket, or set aside, their preconceived

experiences about the phenomenon of interest. Bracketing is also referred to as *epoche*. The phenomenological researcher wants to fully understand the phenomenon from each participant’s point of view. The second step in data analysis is *horizontalization*, in which all significant statements related to the topic are listed and given equal value. In the third step of analysis, the researcher clusters statements into themes and searches for meaning. Synthesis of themes results in a general description of the essence of the phenomenon.

### Ethnography

Ethnography has been said to be the gold standard or hallmark of qualitative research, and it is characterized by in-depth study of a culture’s naturally occurring behavior. While originally developed and employed by anthropologists to study human nature, the use of ethnography may increasingly be seen in the social sciences in general, with developed subfields such as educational ethnography and ethn nursing. Features of ethnography are that the researcher is in the field for long durations of time, uses participant observation to collect data, and examines culture. A long duration of time may be defined as at least one cycle of the phenomenon (e.g., one season, one semester, one treatment cycle). It is important to note that one may use ethnographic methods but may not be conducting a full ethnography. In these instances one may refer to one’s study as ethnographically informed or influenced.

### Case Study

While case study may be considered quantitative, mixed method, or qualitative research, this entry addresses holistic, qualitative case studies only. Case study often seems similar to other types of qualitative research such as in-depth interviews or ethnography. However, case study is distinguished from other research in that it is the intense description of one bounded unit (e.g., one client, therapy group, couple, clinic, organization). The holistic case is naturally occurring and bound to its context. The particular nature of the case is what is of interest to the researcher.

Case studies may be designed in multiple ways. The researcher might choose a case for what Robert Stake has called an *intrinsic* reason or an *instrumental* reason. Intrinsic means that something about the specific case is of interest. Instrumental cases, however,

are chosen to illustrate a general topic of interest. Additionally, multiple or *collective case* studies may be designed in which each case is similar, dissimilar, typical, or different. A *case within case* is a design in which a larger case is explored by examining smaller cases that occur within it. For example, a counseling clinic of interest may be explored by studying three of the counselors within the clinic in depth along with an overall study of all of the features of the clinic such as the caseload, funding, philosophy, and director.

Because it is a study of one bounded unit, generalizability of a case is an ongoing issue for case study research. A case study researcher typically believes, along with the field of qualitative researchers, that the detailed, holistic, rich, descriptive information of their research allows users of case studies to determine to what extent the case generalizes to their situations.

A case study researcher makes a case through the presentation of details that convince the reader and make clear the issues of the case. The small number of cases allows for significant depth of data collection. In holistic case study, data are gathered through observation, interviews, and artifact, whenever possible. Then, information is triangulated and presented in a rich, descriptive case report.

### **Narrative Inquiry**

Jean Clandinin and Michael Connelly have succinctly defined narrative inquiry as “stories lived and told.” Narrative inquiry may also be said to be a study of the generation of stories of life experiences, a discourse form of research in which a story is examined as it changes over time, and an exploration of experience through stories that people tell. Narratives are the unit of analysis. Most narrative researchers define *narrative* as text obtained from in-depth interviews or documents such as journals, diaries, letters, and memoirs. However, some narrative researchers have expanded this methodology to include observational research in which the researcher specifically looks for stories that occur contextually in the field.

Narrative analysis may include a variety of procedures for interpreting narrative data. The text tends to be analyzed using the perspective or techniques of a particular discipline. For example, a sociologist may be interested in the relationship of the narrative to meanings in society, while a counselor or psychologist may be more interested in memory, process of recall, and therapeutic understandings of story.

## **Data Collection**

In order to answer the question “what is going on here?” it is important for qualitative researchers to ask, observe, and even experience as much as possible in order to create rich descriptions of what is happening. In general, qualitative researchers first decide what they want to know about what is going on. If they wish to *discover something*, they may choose a grounded theory approach. If they are *seeking to understand*, they may choose ethnography. A case study would be used if they want to *explore a process*. *Describing the experience* would be accomplished with a phenomenology. If the researchers want to *report the stories*, then a narrative approach would be taken. In general, qualitative research questions begin with *what* or *how*. What is going on here? How does this person relate to the group? In seeking to answer these types of questions, the three common forms of collecting qualitative data are interviews, observations, and examining artifacts.

### **Interviews**

Interviews can be conducted with individuals or with groups that are referred to as group interviews or focus groups. Interviews can be structured, semistructured, or unstructured. Technology has also impacted interviews, so an interview may be face-to-face, over the phone, or through the Internet. Researchers conducting interviews begin with an interview *protocol*, which is a list of questions that will be asked of the participant. In structured individual interviews, the protocol lists each question along with a limited set of response categories. Responses to structured interviews are coded into pre-established categories. Unstructured interviews are in-depth and open-ended and are similar to a conversation with equal give-and-take between the researcher and participant. Unstructured interviews in counseling research are recommended for sensitive topics such as rape or incest and when interviewing young children. Semistructured interviews are a mixture of structured and unstructured questions and are the interview design most qualitative researchers employ.

### **Observations**

Observation is a key form of data collection. Observations range from being nonparticipatory in nature, in which the researcher tries to remain unnoticed, to participatory in nature, in which the researcher joins in on the activities being observed. In both

nonparticipatory and participatory observation, the researcher keeps field notes, or records of observations. Field notes may also be used to record feelings of the researcher. Field notes are considered data and can be synthesized with other types of data such as interviews to help create a complete understanding of the complexities of the cultural group being studied.

### Artifacts

In qualitative research, an artifact is anything made by humans that can be picked up and observed. A cultural artifact is something made by a person or a group of people that gives information about that group. Examining a clinic's physical layout or procedure manual are methods counseling qualitative researchers may use to explore a question. The idea of examining cultural artifacts to understand people emerged from anthropology. In counseling research, an artifact might be a counselor's case notes, videos of sessions, or a client's journal or artwork. When exploring the historical aspects of a participant, the artifact might be an historical document such as a legal document, letter, or diary.

### Analysis

It is important to note that from the first moment qualitative data are collected, analysis should be ongoing and recursive. If researchers wait to analyze the data until all the data are collected, they are missing a key opportunity to take advantage of the emergent, flexible, data-driven process of qualitative research. In other words, as each observation, interview, and artifact is examined, new questions emerge that may guide future data collection. With this in mind, data analysis has two major areas for discussion: data management or the organizing of data, and the process of breaking down, reassembling, and interpreting data through qualitative analysis.

When organizing data, it is vital to make copies of all-important papers and put them in at least two locations. Stories abound of lost data never to be generated again. Researchers are advised to allocate time daily to put field notes and interviews in order, catalogue all documents and artifacts, label and store all data, create a table of contents of stored data, check for missing data, and begin reading through and reviewing data, or what is commonly referred to as read, read, and rereading the data.

An organized set of data allows for analysis to begin in a meaningful fashion. Put simply, analysis

consists of looking for themes, patterns, or categories of similarities. It is important to note that outliers, notes of dissonance, and unique cases are highlighted and not discarded, because the uniqueness of humans is one of the areas of interest in qualitative research.

While there are a multitude of data analysis strategies, some of which were reviewed under the methodologies discussed previously, only one—an overview of Wolcott's analysis—will be presented here. The reader is advised to examine the literature for specific analysis strategies when conducting phenomenology and grounded theory. Wolcott has said that all analysis may be said to be a process of description, analysis, and interpretation. During *description*, the data speak for themselves, and long pieces of the final product are drawn directly from notes, journals, or interviews. The researcher essentially treats descriptive data as facts. While all researchers use description at some level, it is especially useful for concepts that have never been examined in a scholarly manner. *Analysis* then expands and builds on description using some detailed plan or approach to identifying key relationships in the data. Finally, data *interpretation* follows analysis or arises directly from description. During interpretation the researcher does not claim to be as scientific as during analysis and is not as restricted as during the description. Here the goal is to make sense of the data by making interpretations of, inferences from, and implications about the data for the field.

### Trustworthiness

*Trustworthiness* is an overarching term for validity and reliability. Other terms that are used may include *dependability*, *confirmability*, and *credibility*. Validity and reliability of research together compose one of the most hotly debated issues in qualitative inquiry, and they are at the root of many postpositivist researchers' lack of acceptance of qualitative research. Qualitative researchers are advised to have a full understanding of quantitative and qualitative notions of validity and reliability when defending their research. The most important idea to understand is that there are procedures common throughout the field of qualitative research that allow one to feel more confident that the research data presented show a fully fleshed out picture. However, this picture is not more "true" than the picture provided by quantitative data, just more fully explored. The use of most of these procedures depends on the type of research being conducted and the research question being examined. Some of the most

common procedures include member and peer checks, triangulation, audit trail, duration in the field, and reflexivity.

The use of reflexivity may be the most valuable yet least demonstrable way to enhance a study's trustworthiness. Reflexivity is a critical self-reflection on one's biases and predispositions. Researchers are encouraged to explore their bias in a researcher journal. Reflexivity may be a means for critically inspecting the entire research experience.

### Future Directions

In the first decade of the 21st century, there is a new emphasis among qualitative researchers on ethics, personal responsibility, and moral obligation. In general the field is taking on a new participatory, feminist, democratic, and reciprocal stance. Interviews are becoming more a negotiated accomplishment between the interviewer and the interviewee, and observations and artifacts are not seen as fact but as interpretable data.

Researchers are also increasingly blending qualitative and quantitative methodologies in mixed methods studies. While researchers such as evaluators find this a pragmatic design, others contest the blending of two such seemingly polarized paradigms, feeling either that the quantitative data are being used to "prove" the qualitative data or that the qualitative data are unnecessary in a rigorous quantitative design.

The tides are shifting in academia, as new faculty are less traditional than their predecessors in terms of their academic reporting of qualitative research. It is common to write research accounts of what went on behind the scenes in a study in an effort to make research practice transparent and informative to other researchers. This practice is a decided move away from an objective account that reports research results as though they are facts. Autoethnography, poems, performances, and photo methodologies are becoming acceptable forms of reporting qualitative research. Examples include ethnopoetics and photovoice, a method that uses photography to help give voice to those who otherwise would not have one (e.g., children, those with low language skills, non-English speakers).

## QUANTITATIVE METHODOLOGIES

---

Quantitative methodologies can be generally defined as the various procedures used to examine differences between groups and relationships between variables with respect to quantifiable phenomena. The list of potentially quantifiable phenomena is immense and includes any type of behavior, attitude, perception,

knowledge domain, or other extant characteristic that can be measured numerically. Quantitative methodologies are applied across a variety of disciplines in the physical, biological, and social sciences and reflect contributions from the fields of statistics and measurement. Statistics include the procedures employed for summarizing numeric data and testing hypotheses, while measurement encompasses the processes used to assign meaningful numbers to the traits or variables of interest to a researcher.

The types of research designs in which quantitative methods are used include true experiments (also known as completely randomized designs), quasi-experiments, and nonexperimental designs (also termed passive observational or correlational). What differs among these designs is the extent to which the researcher exercises control over certain factors in the study and the extent to which randomization is present. Moreover, quantitative methods can be classified into those used solely for descriptive purposes (i.e., to characterize data in terms of distributional shape, central tendency, and variability) and those used for drawing inferences based on tests of hypotheses.

## Origins of Quantitative Methodology

### *Historical Background*

The quantitative methodologies in current use evolved from various disciplines including biology, mathematics, psychology, sociology, statistics, econometrics, and political science and can be classified broadly into the fields of statistics and measurement. Although the fields do share common roots, given the use of statistical methods in conducting measurement analyses and conversely, the reliance on valid and reliable measures to conduct meaningful statistical tests, the fields of statistics and measurement nevertheless have unique historical origins.

To those who have ever taken a course in statistics, the term *statistics* often conjures images of memorized formulas, lists of rules, and tedious calculations. However, the early history of modern statistics was far from dull, often characterized by volatile ideological and philosophical clashes, bitter rivalries, and in some cases, lifelong enmity among the key players in the development of the field. The first evidence of modern statistical reasoning appeared in the late 17th century, when statistical concepts that provide the foundation for modern statistical theory, such as probability, variability, and chance, were first proposed. Many would

argue that among the most profound developments in the history of statistics were Karl Pearson's mathematical formulation of the correlation coefficient in 1896 and Sir Ronald A. Fisher's first publication describing analysis of variance in 1921. Their work not only incited debate within the statistical community but also served as the impetus for subsequent advances in the field following both Pearson's nonexperimental design tradition and Fisher's randomized experimentation approach. During the past half century, new statistical procedures have extended our ability to study quantitative phenomena by accommodating simultaneous testing of multiple dependent variables (e.g., multivariate analysis of variance), modeling of more complex relationships among multiple variables (e.g., path analysis and structural equation modeling), and analysis of complex data structures (e.g., hierarchical linear modeling and multilevel modeling).

Somewhat parallel to the history of statistical methodology was the development of measurement methodology or psychometrics, which can trace its ancestry to early philosophers such as Plato and to scientists including Galileo who espoused the importance of quantifying physical phenomena. However, many modern measurement principles can be more directly attributed to advances in the field of psychology. For example, Gustav Fechner, founder of quantitative psychology, was among the first to propose methods for obtaining psychological measures under rigorously controlled conditions. Other early contributions to measurement from the field of psychology include Charles Spearman's development of factor analysis in 1904 as a means for understanding intelligence, L. L. Thurstone's scaling methods for measuring attitudes, and James M. Cattell's writings on the importance of large samples as the basis for group intelligence tests. Since the mid-1900s, among the most significant innovations in the field of measurement have been improvements in procedures for estimating reliability, such as the reliability coefficient presented by Lee J. Cronbach in 1951, as well as the realization of item response theory, which now dominates large-scale standardized testing and has made possible advances in the computer adaptive testing that is used with many assessments such as the Graduate Record Examination.

### *Philosophical Foundation*

While some would contend that quantitative methodology stems largely from logical positivism, in fact, quantitative methodology, particularly as applied

in the social sciences, derives primarily from postpositivism. Logical positivists espouse a deterministic view of reality, in which knowledge can be absolutely verified in a world of order and regularity. In contrast, postpositivists view reality as less certain and more probabilistic than deterministic. Researchers using methods of statistical inference likewise operate within a paradigm in which statements about knowledge must be couched in uncertainty and probability. Moreover, another fundamental tenet of postpositivism that underlies statistical practice is Popper's notion of falsification. As any student in a beginning statistics course knows, hypotheses are tested, not for the purpose of verification, but for the purpose of falsification, i.e., a hypothesis can never be proven true but can only be disproven. Thus, the statistical methods that exemplify much of quantitative methodology require a philosophical framework that is considerably less restrictive than logical positivism.

## Concepts and Underlying Principles

### *Probability and Chance*

A basic premise of inferential statistical analysis is the desire to use samples to infer characteristics about a larger population. Because any given sample represents only a subset of the larger population of interest, there is a possibility that the particular sample selected for a study does not adequately represent the population even if the sample is randomly selected. Consequently, there is always an element of chance or uncertainty when attempting to use sample data to estimate population characteristics or parameters. For the same reason, researchers using statistical procedures to conduct hypothesis testing can never be 100% certain that the results of their tests are correct or that the results actually reflect the idiosyncratic characteristics of the sample selected for their study.

This concept of uncertainty in quantitative analysis is the basis for significance testing in statistics and also embodies the risk of committing either a *type 1* or *type 2 error*. Type 1 error is analogous to a false positive and occurs when a researcher wrongly determines that a relationship or difference exists in the data when in fact such a relationship or difference does not exist. It should be noted that such an error does not represent an ethical breach but rather an incorrect finding based on any number of reasons, including features of the study's design, characteristics of the subjects in the study, or violation of one or more

statistical assumptions, where assumptions represent a prescribed set of conditions necessary for conducting any given statistical test. Furthermore, there is always some risk of committing a type 1 error when conducting statistical tests. When researchers set a particular *confidence level*, *level of significance*, or *alpha* prior to conducting their statistical analyses, they are in essence indicating the probability of type 1 error they are willing to risk.

The other type of decision error that is always possible is type 2 error, which is akin to a false negative. Researchers committing type 2 errors fail to detect significant differences or relationships that are actually present in the population. In such cases, their tests are said to lack *power*. Statistical tests may have insufficient power due to various factors, including small sample size, excessively stringent levels of significance, violation of statistical assumptions, the study's design, or unreliable measures of the variables.

Regarding the relative seriousness of the two types of errors, there is no absolute consensus; it clearly depends upon the nature of the study and the potential consequences of the error. For example, in some types of medical research, failure to correctly identify a drug as potentially effective in mitigating a life-threatening illness (type 2 error) arguably might present a more egregious mistake than incorrectly determining such a drug to be effective when it is not. However, by convention, most researchers tend to set their alpha (or risk of type 1 error) at .05 or .01 and type 2 error at .20, suggesting less tolerance for type 1 errors.

### *Variability*

Inherent in the use of quantitative methodology is an interest in understanding variability. In fact, it was curiosity about variation in such diverse phenomena as the size of sweet peas, the chest girths of Scottish soldiers, and the characteristics of hops used in brewing beer that drove development of early statistical theory. Through their observations, scientists noted both regularity and unpredictability in the variation associated with the events they observed. This fascination with variability provides the basis for the current inferential statistical analyses that researchers apply to understand, explain, or predict differences. Such differences might manifest themselves in disparities between groups, changes across time, or relationships between variables. Likewise, the field of measurement is founded on an interest in assessment and classification as a means for comprehending diversity. Consequently, the

presence of differences among the phenomena to be studied is assumed and is requisite to meaningful application of quantitative methodology.

Variability from the perspective of quantitative methodology is often classified into systematic versus random. This distinction in the nature of variability holds true in both statistics and measurement. In statistical analysis, tests of significance typically comprise two components: explained and unexplained variance. The explained component represents variability attributable to factors being examined in the study, such as a treatment effect, motivational influences, and so on, while the unexplained or random component reflects factors outside the control of the study, such as individual differences or environmental distractions. Accordingly, it should be evident that researchers engaging in statistical analyses seek to maximize systematic variance and to minimize random variance, which is often given the status of *noise* or *nuisance*. Likewise, in measurement, the variability in a set of scores, whether from psychological tests or physiological measures, is often partitioned into systematic variance associated with the trait of interest and random error variance due to faulty measurement.

### **Error**

Error is the presence of any type of random or systematic variance that adversely affects a study's outcome or the soundness of a measure. As noted above, there are two different types of decision errors critical to conducting statistical hypothesis testing. However, the concept of error in quantitative methodology comes in many guises. Sampling error, measurement error, and prediction error are among the sources of extraneous variance that compromise the utility of information obtained through statistical analysis and measurement. Concepts of measurement reliability and validity are related to the presence or absence of random and systematic error, respectively. Examples of random errors that could reduce reliability include examinees' mood states, guessing, memory lapses, and scoring errors. In contrast, potential systematic errors that could diminish validity include learning disabilities, reading comprehension, and personality attributes that consistently contribute to either inflated or underestimated scores on various types of measures. Errors in general are considered undesirable in applying quantitative methodology, whatever form they take. Much of the advice on designing sound research

focuses on attempts to minimize the various sources of potential error to the greatest degree possible.

### **Control**

Control in the context of quantitative methodology is essentially the ability to minimize or account for extraneous variability by ruling out plausible, alternative explanations for the findings of a study. Where sufficient control is absent, researchers are unable to unambiguously interpret the findings of their studies. Control can take many forms, including manipulation of conditions within a study, holding certain factors constant, randomization, and inclusion of potentially confounding variables in order to study their effects. Both manipulation and randomization are hallmarks of the experimental research designs pioneered by Fisher. Such designs, which form the basis for evidence-based research, are often dubbed the *gold standard* because of their ability to control for most extraneous variables. Both nonexperimental and quasi-experimental designs are sometimes considered less rigorous because of their inability to adequately control for extraneous factors. Nevertheless, many researchers use these types of designs when the topics for their research do not lend themselves either to manipulation of variables or to randomization.

## **Types of Quantitative Methods**

### **Statistical Procedures**

There is no single taxonomy for classifying the countless statistical procedures that have been or currently are in use, and compilation of a complete list would be daunting. However, several classification criteria can be used that illustrate features of different methods. For example, statistical procedures are often dichotomized into *descriptive* versus *inferential*. Within inferential statistics, procedures are often organized according to how variables are measured (e.g., whether they are categorical or continuous), whether analyses involve one or more than one independent and/or dependent variable, whether data are collected at one point in time or at two or more points in time, or to what extent assumptions are made about underlying characteristics of the data. Examples of commonly used statistical procedures include analysis of variance to examine mean differences among groups, chi-square test of independence to analyze associations

between categorical variables, and multiple regression to determine the extent to which a set of variables explain or predict some outcome. Newer, more complex multivariate procedures that have begun to see greater application in the past few decades include structural equation modeling, hierarchical linear modeling, and growth curve analysis.

### Measurement Procedures

Measurement procedures are quantitative tools used primarily to evaluate reliability and validity in order to determine the appropriateness of scores for a given purpose and population. Traditional approaches to assessing reliability include Cronbach's alpha and the test-retest method. In some settings, procedures based on item response theory (IRT), have replaced traditional methods. Although originally used almost exclusively with large-scale tests, IRT-based methods, particularly Rasch analysis, have become increasingly popular for analyzing scores from affective measures such as personality inventories and attitude scales. Validity-related procedures comprise a variety of techniques, including factor analysis, correlations, and other statistical methods to provide support for the meaning and appropriateness of scores from a particular measure.

### The Future of Quantitative Methodology

Given the emphasis on evidence-based research that is currently being mandated in a number of arenas, it is likely that quantitative research will continue to flourish. The No Child Left Behind legislation as well as other federal directives not only emphasize the application of randomized trials but also stipulate use of instruments producing valid and reliable scores,

implying a preference for quantitative outcome measures. In addition, with increasing computer capabilities, technology is allowing development of sophisticated statistical and psychometric methods that will enable quantitative researchers to analyze their data in ways researchers cannot currently envision. Twenty years ago, for example, hierarchical linear modeling was primarily a concept; now it is seen in an increasing number of applied studies to capture more accurately data that are clustered in some hierarchical fashion, such as occurs when students all experience the same classroom or clients share the same therapist. It is likely that future developments in quantitative methods will continue to expand our ability to understand the complexities of behaviors, events, and processes as well as their interrelationships to the extent that such phenomena can be quantified.

## **RECRUITMENT: HISTORY AND RECENT TRENDS IN DIVERSITY**

---

Early in the history of the psychology/counseling profession, few efforts were made to “recruit” culturally diverse persons; rather, diverse persons, typically through grassroots and organizational efforts, sought entry into psychology despite major resistance. This was especially true during the late 19th and early 20th centuries. However, as time has passed, especially within the last 3 to 4 decades, more of a concerted effort to attract diverse persons has been made by professional mental health organizations.

The U.S. civil rights movement in the late 1960s was instrumental in raising awareness within psychology and counseling that the academic and professional ends of the fields might not be effectively meeting the needs of certain diverse groups, especially women and individuals from groups that differed racially or ethnically from the majority. This realization led to a focus on diversifying the personnel in the professions and the recruitment of persons from underrepresented groups.

However, this early recruitment effort did not immediately extend in equally forceful ways to all groups. For example, LGBT (lesbian, gay, bisexual, transsexual) individuals were not initially included. In addition, although women were initially an underrepresented group, the discipline of psychology is actually now more popular with women than with men at the undergraduate and graduate levels, especially within the applied branches. So, in the 21st century, the idea of who is underrepresented has changed, and

males are now considered underrepresented persons in psychology and counseling.

At the current time, there are many divisions of the American Psychological Association (APA) and special interest groups within the APA that focus on diverse groups, such as persons with physical disabilities (Division 22; Rehabilitation Psychology), persons from outside the United States (Division 52; International Psychology), persons with neurocognitive disorders (Division 33; Mental Rehabilitation and Developmental Disabilities and Division 40; Clinical Neuropsychology), men (Division 51; Psychology of Men and Masculinity) as well as more traditional demographic groups such as women (Division 35; Psychology of Women), LGBT persons (Division 44; Society for the Psychological Study of Lesbian, Gay, and Bisexual Issues), and people of color (Division 45; Society for the Psychological Study of Ethnic Minority Issues). In addition, the APA Public Interest Directorate also has committees focused on women (established in 1973), on LGBT persons (established in 1980), on persons with disabilities (established in 1985), and on socioeconomic status (established in 2006), among others.

The profession of counseling, represented by the American Counseling Association, also has specialty divisions focusing on diverse groups of people, such as the American Rehabilitation Counseling Association (established in 1958), the Association for Multicultural Counseling and Development (established in 1972), the Association for Adult Development and Aging (established in 1986), and the Association for Gay, Lesbian, and Bisexual Issues in Counseling (established in 1997).

## Recruitment of Women

Without question, the culturally diverse group with the most long-standing matriculation into psychology would be women, specifically European American women. The initially limited U.S. academic programs in psychology at the end of the 19th century (e.g., Johns Hopkins, Harvard, Columbia) were staffed solely with European American men, most frequently operating experimental labs focused on sensation and perception, physiological psychology, and learning and memory; these labs were patterned after those labs in which they trained in Europe. The entry of women into the ranks of psychology was a slow process, one pioneered by several outstanding female scholars such as Mary Caukins, Christine Ladd-Franklin, and Margret Floy Washburn. Even after these women proved to be psychological scientists par excellence, it still took several years before most academic training programs became truly coeducational. The application of psychology to everyday life and psychopathology, championed in the United States by Lightner Witmer and Hugo Munsterburg during the late 1800s, as well as Sigmund Freud's first and only visit to the United States to discuss his "talking cure" at Clark University in 1909, opened the doorway for the beginnings of clinical psychology and ultimately, from the 1960s on, the pathway for large numbers of women to matriculate into applied psychology training programs.

## Recruitment of Persons of Color

The recruitment of persons of color in psychology has largely highlighted the bringing of African Americans into the discipline; this parallels the focus of racial issues in the general U.S. society during the past 50 years as being predominantly about Black-White race relations. In 1963, an APA Ad Hoc Committee of Equality of Opportunity in Psychology was established to examine racial inequality in the discipline. Soon thereafter, in 1970, the Association of Black Psychologists (founded in 1968) developed a 10-point program for graduate departments of psychology as an effort to increase African American representation.

This initial recruitment effort by the APA aimed toward persons of color underwent a metamorphosis and expansion over the next few decades via the creation of the APA Ad Hoc Committee on Minority Affairs (1971), the APA Office of Ethnic Minority Affairs (OEMA, 1979), the APA Board of Ethnic

Minority Affairs (BEMA, 1980), and the APA Committee on Ethnic Minority Affairs (CEMA, 1990). The APA Public Interest Directorate also has a specific arm of the discipline focused on recruitment and retention of individuals from racially and ethnically diverse groups, the Committee on Ethnic Minority Recruitment, Retention, and Training in Psychology (CEMRRAT), established in 1994.

Changes in U.S. demographics over the past decades—specifically the sharp increase in numbers of Latino, Spanish-speaking persons, which has made this group bigger than that of African Americans—will likely bring more efforts to matriculate Latinos and Spanish speakers into the discipline. In addition, the increasing numbers and awareness of unique needs across all racial groups will likely bring more focus on Asian Americans and American Indians as well as on the many subgroups of the Latino group (e.g., Mexican, Puerto Rican, Cuban, Central and South American), Asian (e.g., Chinese, Japanese, Korean, Vietnamese, Thai) and American Indian (e.g., Cherokee, Choctaw, Chickasaw, Comanche) groups.

There are psychological organizations outside of APA for non-African American racial and ethnic groups, such as the National Latino/a Psychological Association, the Asian American Psychological Association (founded 1972), and the Society for Indian Psychologists, which parallel the mission of Association of Black Psychologists. Professional counselors may have state caucuses that focus on special interest groups (e.g., Black counselors)

## Recruitment of Lesbian, Gay, Bisexual, and Transgendered Persons

With respect to LGBT persons, this population was pathologized to a degree that outdistanced even the immense biases present in U.S. psychology (and society) against women and people of color. Homosexuality was defined as a mental illness until 1973 when the *Diagnostic and Statistical Manual of Mental Disorders* of the American Psychiatric Association formally removed the official disorder from its text (replacing it with the category of ego-dystonic homosexuality) and the American Psychological Association endorsed this new perspective for its own professional discipline in 1975. In the recent *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV)* and *Diagnostic and Statistical Manual of Mental Disorders,*

*Fourth Edition, Text Revision (DSM-IV-TR)*, homosexuality is no longer included specifically as a mental disorder, albeit the category of Sexual Disorder Not Otherwise Specified has “persistent and marked distress about sexual orientation” listed as an example of a situation warranting this diagnosis.

Although the awakening of psychology and counseling to its discriminatory position brought much needed attention and advocacy to LGBT persons and their psychological needs in the ensuing decades, the longstanding viewing of homosexuality as a mental disorder also suggests a lack of active recruitment of LGBT persons into the professions before the early 1970s.

Kimmel and Browning, in a historical review of APA Division 44, identified several initiatives put in place to support psychology students and professionals once they are in the pipeline; however, it is not as clear that specific efforts have been made by APA to actively recruit LGBT persons into the discipline and profession equivalent to those made to diversify the gender or racial balance of the discipline. Division 44 has historically provided a formal mentoring program, a divisional listserv, and informal programs at annual APA conventions as avenues to extend a warm and inclusive welcome to LGBT-affirming persons within psychology. Recent data from the APA Office of Research suggest that APA Division 44 enjoys a good number of student affiliates and members, indicating that many psychologists and psychology trainees are taking advantage of what this division has to offer.

### Future Directions

The field of psychology and counseling has made significant strides in diversifying its professional ranks as well as in eliminating oppression and discrimination against persons from culturally diverse groups. However, there is still a lack of parity within specific diverse group domains (e.g., race/ethnicity) and across diverse group domains (e.g., race/ethnicity, sexual orientation, sex) in terms of the extent to which professional organizations are expending resources to recruit diverse members into their ranks. The APA, for example, reports that the majority of students matriculating into psychology are women, but that people of color and LGBT students and trainees still are comparatively much less well represented. This lack of parity notwithstanding, the future looks hopeful in that there is increasing movement toward an approximation of

demographic variability within these mental health professions that more accurately reflects the demography and life experiences of the clientele they serve (and need to serve) in our society.

## RETIREMENT, IMPLICATIONS OF

---

Retirement refers to an ongoing period in life that traditionally has been considered to begin at the point of withdrawal from work life. Retirement is a social concept implemented primarily during the past 100 years due to changes in life expectancies and population demographics. The increase in life expectancies over the past century has produced both challenges and opportunities during the retirement phase of life that continually require increased attention and resources. The arrival of the baby boom generation at retirement age has enormous implications for population demographics, the workforce, and a host of social and economic issues. A dramatic trend toward earlier retirement, coupled with increased life expectancy, ensures a growing focus on issues related to retirement. The fact that the average American can now expect to be in retirement for 15 to 20 years creates demands that no other generation has faced. Retirement has broad social and cultural implications.

For individual retirees, this period of life holds remarkable potential and risk as well.

The usual definitions of retirement address withdrawal from the workforce and the remaining years of life. Operationally, retirement has been conceptualized in a variety of ways: (a) a well-deserved rest as a reward for years of work, (b) a means of maintaining an effective work force, (c) a period of transition to old age, (d) a distinct period of human development, (e) a period for postretirement careers, and (f) a period of adjustment to loss of work identity. Perhaps all of these are applicable across or within particular cases. The development of a general theory or model for retirement has been difficult for several reasons. For example, the number of factors that influence the nature and quality of the retirement experience is substantial. Further, there is no real standard for the onset of retirement. Some workers choose to retire early; some choose not to retire at all; others are subject to forced retirement; some retire partially; and some return to work after retirement.

### Factors Influencing Retirement

Several specific factors interact to influence individuals' experience of retirement. These factors include finances, health and medical care, relationships, housing, existential issues, security, and satisfaction with career. Obviously, these factors are highly interrelated in regard to their impact, but they will be described individually.

#### *Finances*

The financial basis for retirement is probably near crisis levels for a large proportion of the population. Social Security was intended to be a supplemental source of income for retirees, but future recipients are likely to face reduced funding and delayed eligibility. Pensions have been another major source of retirement income, but now only about one fifth of working Americans will receive pension benefits. More recently, there has been a major shift toward personal savings to finance retirement, and this trend is being further encouraged by the federal government. Reverse mortgages have become a popular way to supplement Social Security and savings for many retirees. A reverse mortgage is a loan that enables senior homeowners to convert part of their home equity into tax-free income without having to sell

their home, forfeit title to it, or make monthly mortgage payments. Part-time employment for those who are able to work is becoming more common. Given the rapid shift toward personal mechanisms for funding retirement, an emphasis on early career planning is essential.

#### *Health and Medical Care*

The ongoing explosion of medical and pharmaceutical costs has a large, disproportional impact on retired persons due to their almost inevitable and disproportionate healthcare needs. Relatively few retirees have the personal savings required to cover a catastrophic illness without health insurance coverage, which can be very expensive to maintain. The Medicare program is a source of help to retirees over age 65, but satisfaction with the system tends to be low among recipients, and many healthcare providers have reservations about the system. It is clear that secure healthcare services are an essential component of the retirement experience.

#### *Relationships*

Aging itself is correlated with loss of important familial, professional, and personal relationships for a variety of reasons. Geographic mobility has greatly disrupted close, extended family relationships. Shifts away from inclusion of the elderly in their children's homes toward profit-based residential facilities often leads to reduced contact with children and grandchildren. Loss of a spouse to death can have an enormous emotional impact on retirees. Given that social withdrawal can precipitate or exacerbate depression, the maintenance of healthy, reciprocal relationships is essential.

#### *Housing*

A fundamental decision facing retirees is where they will live and in what form of housing. Many retirees choose to relocate geographically after completing careers. Relocation decisions may be driven by a desire to live in a more preferable climate, availability of recreational activities, proximity to family and friends, etc. Clearly, major relocations must be carefully considered and planned before being undertaken. One model is to vacation in selected locales on a trial basis prior to retirement.

Wherever retirees choose to live, there are many types of housing from which to choose. Maintaining a single family home is, of course, a possibility. As physical abilities decline, maintenance of homes and yards can become taxing. Condominium options, duplexes, and patio or garden homes where maintenance and lawn care are provided can be attractive and practical choices. More recently, communal arrangements are being piloted in which several retirees share a single housing unit. Such arrangements offer opportunities for sharing costs and providing for common needs. Retirement facilities now offer multiple forms of housing to accommodate residents in need of various levels of support and assistance. Generally, costs increase corresponding to needs. Clearly, financial planning for the duration of retirement needs to include contingency plans for increasing levels of care and support. Many preretirement options are being offered by insurance companies to provide for long-term care costs for the elderly.

### ***Existential Issues***

The struggle to find and maintain meaning in life continues to be central for many people throughout retirement. The prominence of these issues in adjustment to retirement across individuals will likely vary considerably. For example, individuals who derive meaning and personal identity heavily from their careers can expect some sense of loss after full retirement. Partial retirement is sometimes attractive to such people. For others who view work primarily as a means for achieving financial goals, retirement may represent a dramatic increase in freedom. In any case, engagement in satisfying and meaningful activities during retirement is essential to fostering a sense of well-being. Religious, volunteer, and family-based activities are all means by which individuals can pursue fulfillment. Inactivity and social withdrawal are typically self-destructive in this regard. Both mental and physical activity have profound effects on many dimensions of physical and psychological health, especially during the retirement period.

### ***Security***

Security needs are fundamental for most people. During the retirement phase, as health, relationships, and independence may decline, the need for psychological security may be expected to increase. Security

needs exist on several levels. Physical protection against abuse or exploitation is perhaps most basic. Many strategies exist in financial planning to protect assets. Housing choices have to include provisions for physical security. Particularly when financial resources are limited, security needs can be more challenging. Involving family, friends, and professionals in evaluating risks and ensuring freedom from exploitation and abuse may be advisable. Older retirees, in particular, may become the targets of predatory exploitive schemes. Unfortunately, family members themselves are often perpetrators of the exploitation of their parents and grandparents. The size of the problem is substantial, with approximately 70% of the nation's wealth controlled by people nearing, or already in, retirement. The use of professionals outside of the family, primarily certified public accountants (CPAs) and attorneys, can ensure effective protection of assets. The problem of exploitation of the elderly has become so concerning that Congress is currently considering legislation like the Elder Care Act to protect seniors from exploitation.

### ***Career Satisfaction***

Retirement, as a stage of life, is affected by the level of career satisfaction one has achieved. This aspect of retirement planning and preparation should be carefully considered. The kind of meaning one seeks in retirement is likely related to the level and kinds of fulfillment already experienced. One central aspect of retirement preparation is to reflect upon what has been satisfying or missing in one's career life. Retirement activities can build on accomplishments and provide for realizing unmet goals. Disappointments need not be ignored, and retirement can be designed to provide for personal fulfillment as the individual defines it. The career experience is typically a major influence upon this definition.

### ***Lifetime Perspectives***

There is a clear trend toward viewing retirement as an integrated developmental period of life. Increased life expectancies and improved health care have led to the extension of retirement for most people. This extension applies not only to years, but also to options and choices of lifestyle. As a continuing period of life, retirement is greatly affected by earlier periods and experiences. This may be most true in terms of the financial circumstances of retiring people.

There are literally thousands of Web sites devoted to planning for retirement, and a vast majority of these Web sites relate to financial planning. The evolution toward individual savings plans as a model for financing retirement is placing heavier responsibility on the individual for financial planning. The range of investment options with their associated risks and benefits makes the use of financial planning professionals a wise choice for most people. Many employers already provide retirement counseling services for employees for this purpose.

*Save early and save often* is a catchphrase that is often used for financial planning for retirement. Whether one is salaried or self-employed, there are major tax incentives for longer-term savings for retirement. The exponential growth of savings invested early in one's career adds further credibility to the catchphrase.

Financial conditions will have a major bearing on several dimensions of retirement. However, optimizing the retirement experience requires personal preparation and planning beyond the financial dimensions. One of the fundamental realities of retirement is that retirees will almost always have to assume more responsibility for structuring their time and activities after they leave the world of work, where such structure was largely provided for them. Leisure activities, for example, will typically increase in importance during retirement. Individuals are much more likely to have meaningful leisure activities in retirement when they have a well-established leisure history. Further, as individuals grow older, having several varied types of leisure activities can be useful. Given the profound and consistent relationship of physical activity to mental and physical health among the elderly, well-developed leisure patterns in midlife greatly contribute to quality of life in the retirement years.

Naturally, there are tremendous individual differences in personal needs, preferences, and motivations in retirement. *Lifestyle planning* is a broad term used to encapsulate the major dimensions of personal circumstances into the retirement years. Lifestyle planning encourages individuals to project a well-developed vision into retirement by answering a series of key questions:

1. What are the parameters of my financial resources?
2. What roles do important family and friends play in meeting my needs?
3. How might my retirement affect significant others, e.g., spouse, children?
4. What climate or locale best supports my envisioned retirement lifestyle?
5. Does part-time work fit into my lifestyle in meeting needs (e.g., productivity)?
6. How are my support needs likely to evolve over 5, 10, or 15 years of retirement?
7. What level of activity would I like to maintain across different areas?
8. Are there things I believe I have missed in life? How can retirement address these?
9. What are some concrete things I'd like to do? For example, would I like to travel, write, learn, or teach?
10. What am I grateful for in my life and how can I share that with others?

Retirement can lead to a sense of social isolation, especially when work relationships have been primary or retirement involves a geographical move. Social support systems are critical to most people. The need for social support also changes across the retirement years and requires some significant planning and adjustment. It is generally advisable to begin discussing retirement issues and plans with friends and family before the time to retire actually occurs. Access to family or others who will play a supportive role in retirement is a key dimension of satisfaction; consequently, everyone ought to be involved in the planning process. Certain support, with financial matters for example, may be best handled through professionals. From the perspective of generativity, retirees also need to make plans for contributing to the support of significant others (e.g., spouse, children, siblings). What needs might these individuals have for which the retiree would want to share responsibility?

The substantial increase in the numbers of retirees who return to work, at least part-time, reflects shifting financial demands. Others, though, choose to return to work for a variety of reasons. For example, they may see work as an opportunity to help others; to meet achievement/productivity needs; to stay engaged cognitively and socially; to share knowledge, skills, or experiences; or to gain the intrinsic rewards associated with engagement in work. Any of these objectives can also be met by doing volunteer work as well. The objective is for any work activities to be thoughtfully planned. Retirees returning to work ought to consider both the reason for assuming work responsibility and their specific expectations regarding the work.

It is very normal for retirees with a lifetime of experiences and increased free time to reflect on the meaning of life. The reality of mortality increases with age as well. Retirement can be a great opportunity, not only to reflect on purpose of life issues, accomplishments, and failures, but also to develop and project a vision of the future. Sharing the reflections of retirement with younger generations, staying engaged with social and religious institutions and activities, and engaging in service to others are all easily accessible ways of enhancing the meaningfulness of life in retirement. Of course, these skills, abilities, and motives are established and nurtured earlier in life.

## ROEHLKE, HELEN J. (1931– )

---

Mentor, role model, supporter, founder, leader. Few people have the ability to touch the lives of others and to make positive changes in the world around them.

This will be Helen J. Roehlke's legacy to counseling psychology. Her gift to the field extends far beyond her scholarship and service through the impact she had on the lives of the graduate students and interns whom she trained and the professionals she mentored during their early career years. She was passionate about training the next generation of psychologists and dedicated a great deal of her professional time to mentoring and supporting students from underrepresented groups, particularly women; individuals of color; lesbian, gay and bisexual persons; and international students and young professionals. Throughout the span of her career as a counseling psychologist, Roehlke saw the field transform from a monocultural profession to one that promotes and encourages diverse perspectives and individuals from varied backgrounds. She inspired and touched students' lives and made a valuable contribution to the training of professionals in counseling psychology through her mentoring and guidance of generations of psychologists.

### Family Background

Roehlke was born in Chicago, Illinois, to Enriqueta and William Jackson. She was raised in a household with two working parents; her mother did office work and bookkeeping and her father was an accountant and tax consultant. She was the older of two children, but was raised as an only child due to the 15-year time span between her birth and that of her younger sister, Ginny.

Roehlke met her husband, Art, during her junior year at Carleton College, and they married in the summer of 1952 following their college graduation. They moved to Columbia, Missouri in 1955 and have lived in that area for over 50 years. They have three sons, Kurt, Kent, and Adam, and three grandchildren, Jake, Lauren, and Brennen.

### Educational Training Background

Throughout her elementary and secondary education, Roehlke was a good student and performed well academically. Her mother was an avid reader and always had books at home, so Roehlke learned to love reading at an early age. She received a great deal of encouragement and support for attending college from her parents and teachers as well as from a great aunt who was particularly influential in directing her toward higher education. This great aunt bought Roehlke books on literature and poetry when she was growing

up and discussed them with her, sparking Roehlke's early interests in this area. As a woman who was independent and who had traveled the world, her great aunt also helped to nurture Roehlke's career goals as a young woman.

At the suggestion of a young female physical education teacher in high school, Roehlke explored small liberal arts colleges in the Midwest for her college education. She received a number of scholarships from many of these schools and chose to attend Carleton College. As the first person in her family to attend college, Roehlke embarked on her postsecondary education at the young age of 16 and began as an art major. She received a bachelor's degree in 1952 with English literature as her major and psychology as her minor area of study.

Roehlke's venture into graduate study initially began because she wanted to avoid teaching English to high school students. While her husband was working on a master's degree in psychology at Drake University in Des Moines, Iowa, she worked as a psychometrist at the counseling center and enrolled in several master's level psychology courses. Upon completing his master's degree, Art applied and was accepted into the doctoral program in the psychology department at the University of Missouri, and the couple moved to Columbia. Roehlke received a stipend in the rehabilitation counseling program and completed a 60-hour master's degree in 1962. She entered Missouri's doctoral program in counseling psychology right after obtaining her master's. She was one of the few female graduate students working toward a doctoral degree at the time. In fact, only three women had received doctorates in counseling psychology prior to Roehlke. At this time, many faculty believed that doctoral level positions should not be made available to women, because they would just get married, have children, and leave the field. These attitudes made it particularly difficult for women in academia, and they received little encouragement from faculty for pursuing doctoral degrees and following their career dreams.

### Professional Accomplishments

Roehlke spent her entire professional career in Columbia, Missouri, and is widely recognized for her contributions to teaching, research, training, and service. She has numerous research publications and conference presentations focused primarily on clinical supervision, internship training and education, pre- and

postdoctoral accreditation, and counseling women; gay, lesbian and bisexual individuals; and international students. She also taught beginning and advanced practica and supervision courses for doctoral students in the program.

Roehlke coauthored, with Elizabeth Holloway, a seminal article regarding predoctoral internship training in psychology. Cutting-edge publications in supervision addressed effective supervisor behaviors, developmental approaches to teaching supervision, and intern level cross-racial supervisory relationships. Roehlke was one of the pioneering scholars in clinical supervision, and her conceptual and empirical work in this area was groundbreaking at the time. She also contributed to counseling psychology scholarship via her role as a reviewer. Roehlke was an editorial board member of the eminent journals in the counseling psychology field, *The Counseling Psychologist* and the *Journal of Counseling Psychology*, and she continues to serve as an ad hoc reviewer for both journals.

Selected examples of her service to the American Psychological Association's (APA) Division 17 (Society of Counseling Psychology) include Membership Committee chair, Fellows Committee member and chair, APA Awards Committee member and chair, and Division 17 delegate to the cross-specialties Inter-Organizational Committee (IOC). She was also a member of Division 17's Board of Directors while serving on APA's Council of Representatives, and she was on the Board during the planning and final restructuring of Division 17.

Some of Roehlke's founding activities in her early career included being one of the founders of the American Personnel and Guidance Association's Committee on Women and the American College Personnel Association's (ACPA's) Committee on Women; supporting the establishment of a Gay, Lesbian, Bisexual, Transgender (GLBT) Section in ACPA and being a member of this section; being one of first members of both Division 17's GLBT Special Interest Group (SIG) and its Section on Racial and Ethnic Diversity, and sponsoring the GLBT SIG to become a section while serving on ACPA's Board of Directors.

Roehlke was internship training director at the University of Missouri's counseling center for 25 years beginning in 1975. In her early years as training director, she recognized a need to organize other training directors, and she became one of the founding members of the Association of Counseling Center Training

Agencies (ACCTA). Known as the “mother of ACCTA,” Roehlke served as ACCTA’s second president for 7 years, from 1978 to 1985, and continued to serve this professional organization in various roles (i.e., as executive board member, liaison to APA’s divisions 17 and 44, trainer for accreditation site visits, and senior advisor) until she retired. In 1999, ACCTA established an annual award in her name (Helen J. Roehlke Lifetime Achievement Award) to honor a member who “exemplifies the spirit of ACCTA and through [whose] work [has] shown unwavering enthusiasm, commitment, support, and overall service to the organization and profession.”

During her years as training director, Roehlke was also involved with the Association of Pre- and Postdoctoral Internship Centers (APPIC). She was on the planning committee for the first national conference on intern training and was a delegate to that conference. She was also selected as a delegate to both the second and third national intern training conferences as well as to the first postdoctoral training national conference.

Due to her outstanding contributions to the field of psychology at the national level, Roehlke was recognized as a fellow of three divisions of APA: The Society of Counseling Psychology (Division 17) honored Roehlke in 1991, Psychotherapy (Division 29) honored her in 1994, and the Society for the Psychological Study of Lesbian, Gay, and Bisexual Issues (Division 44) honored her in 1999.

In Roehlke’s fellow’s address for Division 17, titled *The Counselor Is a Woman: From Analogy to Actuality*, she described her first-hand witnessing of the profession shift from a predominantly male-dominated field to a predominantly female-dominated field. In spite of the cosmetic changes apparent in the field, the needs of female students were still largely being ignored. Roehlke challenged the field to develop training and learning environments that were open and affirming to all students. The topic of her address reflected her advocacy efforts in allowing access into the profession to a wider circle of individuals than were admitted at the time when she entered the field. Following a format that a few women in the previous 2 years had used, her address also was noteworthy because of its personal nature; this was significant because it was uncharacteristic of previous fellows’ presentations. Today, fellows’ addresses have become a conference highlight largely because fellows are more likely to share aspects of their personal side.

Although she was widely recognized for a number of professional accomplishments and contributions, Roehlke had a profound impact on psychology training and practice as evidenced by her receiving in 1988 the distinguished John D. Black Award for Outstanding Contributions to Professional Practice, the highest practice award in APA’s Division 17. Roehlke represented a professional whose behaviors and practices were consistent with her values and beliefs. She expected the profession to embrace multiculturalism, and she demonstrated this by providing genuine support and encouragement to graduate students of color as well as to lesbian, bisexual, and gay students and to international students. Due in large part to her own experiences as a graduate student and the relative lack of support she felt as a woman in pursuit of her academic and career goals, Roehlke was keenly aware of and attuned to students’ needs and served as a valuable resource for scores of students. At her retirement party in the summer of 2000, many of these students acknowledged the importance of Roehlke’s presence and guidance during their graduate studies and early professional career development.

## RURAL PRACTICE, CHALLENGES OF

---

The United States defines “rural” communities as those of 2,500 people or fewer. A more natural definition is tied to population density: People who live in geographically isolated, low-population areas where occupations are tied to natural resources have more in common with each other than they do with people in cities and towns of any size. The small size of their communities is key to understanding the vibrancy and tenacity of rural people as well as the peculiar dynamics of relationships and types of problems they experience.

Related to rural and farm life are unique pressures and stressors such as economic issues associated with the weather, lack of control over prices, cost of inputs, drought, disease, land costs and rentals, globalization, rural values, and social dynamics. The mental health community needs to be prepared to care for these people and help them with transitions and other stressors so that they can cope effectively.

### Rural Values

Values that undergird rural life tend to be social, based on the family and the community. The social and relational parts of rural life can be powerful in their psychological rewards. Rural people tend to understand what it means to belong to a close-knit community. They put stock in being a good neighbor. They have lifelong relationships with relatives close by and friends who seem like family.

Rural life tends to be characterized by rituals. Most often these rituals concern farming life: sowing and harvesting. They also concern social life: Young people becoming old people in the same place. Rural people accept the interplay between the good and the bad, accommodate themselves to the reality they see, and do what is necessary to be in harmony with their environment.

Rural people often participate in national affairs with great distinction. They offer wisdom in knowing how things fit together, a sense of continuity and history, a restraint against a rush toward change, and an awareness of how decisions will affect the lives of ordinary people.

In addition, rural people may be considered to be place-bound. To be removed from place can be a disorienting experience. One's importance may be diminished, and by being separated from place, one may lose the vital energy upon which one has come to depend for nourishment, strength, and even life. A high percentage of farm families who are forced out of farming stay in their local communities—possibly because of this characteristic. They may view moving to an unknown place, where they do not know the history and the people, as a drastic uprooting. They may fear not knowing how to act in a place where “place” may not be important.

### The Downside of Rural Life

In studying the social dynamics of a small community, psychologist Roger Barker found people take on many social roles to meet community needs. Functioning in multiple roles adds to stress. The same person may serve on different boards and community organizations and as a member of various groups. People may be recruited and pressured into community service.

At the same time, community members often see and meet each other at church, school functions, games, stores, dealerships, card parties, weddings, funerals, community fund-raisers, and local cafes and bars. They “change hats” frequently and make subtle shifts in relationships depending on the roles they are playing.

Rural people may cope with complicated social relationships when goals and ideas come into conflict by being “nice.” Being nice means not engaging in controversy and not giving strong opinions. It means ignoring conflict and living with the differences. In short, rural people often ignore their own feelings or underplay their emotional responses. Being nice is the socially correct way of living in a rural community; to be other than nice invites criticism.

A second concern is nonconformity. To feel out of step, judged, or excluded is painful. People in rural areas who have differences with their communities often live lives of pain, resentments, and anger, because they fear the pathway to reconciliation will

cause further and perhaps irreparable harm. They may live with private anger and opinions that they keep to themselves.

A third concern is avoiding personal risks. Those who have difficulty controlling their emotions or resolving conflict find it easier to keep the peace. Being nice means they don't have to think, take a stand, or risk rejection. If strong feelings and opinions are spontaneously expressed, a rural resident will likely encounter his or her antagonist later in various social settings. The tension between them may be awkward, as it may not be easy to keep roles and agendas separate.

Everyone has vested interests. If one opposes someone strongly in one setting, he or she may block one's goals in another. Strong political controversy can rip apart the social fabric of a rural community. People may not know how to act when lines of conflict divide the community. To be highly passionate on an issue may create tensions one lives with today, tomorrow, and possibly all throughout life. Harmony is the value that makes the rural community work. Even if power is concentrated and public interest isn't served, it still seems better to most people than raw, open controversy that upsets the social system.

A related concern is avoidance of conflict. When controversy spills over into the public arena, people may not know how to act. They may become polarized by the controversy. They may personalize the issue and take sides. They may not have enough experience with conflict to know how to negotiate or search for middle ground. Where does suppressed hostility and anger go? How does the community make important decisions and avoid community controversy? Unfortunately, gossip, social ostracism, and other indirect means of aggression may occur.

Some of the common dilemmas and problems facing people in rural communities are as follows:

- Dealing with powerful social expectations and pressures
- Finding it difficult to say no
- Not feeling reinforced for engaging in leisure or specialized interests unless community obligations are fulfilled
- Being expected to participate in time-consuming social and community events
- Being too successful in a community where others are easily threatened
- Being judged by social comparisons to peers in the local community
- Becoming easily upset or disturbed by adverse public opinion
- Maintaining appearances at a personal cost of being unauthentic; not feeling emotional safety in expressing feelings, problems, or divergent opinions—being criticized for being too open, spontaneous, and honest
- Getting behind a mask—social gain at the personal expense of stifling true opinions and feelings
- Not being able to solve problems because conflict itself is viewed as harmful—greater ease in covering up a problem than in getting people to try out poorly developed conflict-resolution skills
- Being too different or out-of-step with strict community standards

An urban person might say, “Who cares what other people think?” A rural person knows there is social accountability and obligation.

## Counseling in Rural Areas

Life in rural communities has its own value system with unique pressures and stressors. Social obligations, leadership, and volunteering associated with responsible community life lead to very busy, stressful lives. Another issue is the rural economy. The rural economy continues to suffer because of out-migration, declining population, and consolidating forces in the larger economy. Depression and anxiety are common problems when personal or business finances are precarious. Finally, complex technology, expensive inputs, seasonal pressures, the combination of the work and home environments, labor shortages, supervisory responsibilities, and other on-farm enterprises and off-farm employment all test the compatibility and coping skills of farm families.

Rural marriage problems also occur. The interplay between the demanding profession and being self-employed while working at the family residence can create marital conflict. Some male farmers are single-minded in their approach to farming and neglect the emotional needs of their spouse and children. Counselors have to give weight to the very real responsibilities and pressures farmers feel and to give voice to the spouse's need for a warm and nurturing relationship.

Another area of concern is helping farm families work effectively in intergenerational and multifamily farm and ranch operations. There are boundary issues as family members work out common goals and

share a common enterprise. Problems can build and create tensions and resentments while solutions may be stymied by poor communication and problem-solving skills.

The anonymity issue and accessibility of services are also counseling obstacles to overcome. There may be denial about depression, family problems, and alcoholism. There is a strong stigma about admitting a drinking problem rather than a mental health problem. Family doctors and mental health professionals become gatekeepers for the alcohol and substance abuse professionals. The social acceptability of alcohol use for adults and teens in many rural social situations can add to personal problems. While rural communities do not have a corner on alcohol problems, a lack of entertainment and recreation activities can lead to the use of alcohol to enliven social life. Some people are vulnerable to alcoholism or to the social pressures that go with regular drinking.

What are necessary skills for rural counselors? These counselors need to be approachable and down to earth. Effective counseling may be difficult if clients perceive counselors as being better than they are. Being respectful makes a huge difference. Counselors also have to be real and genuine. Additionally, being conversant and knowledgeable about rural dynamics and relationships can set clients at ease. Most clients do not want to feel as though they must educate their counselor about their problem. For most rural clients, travel is not an obstacle in seeking the right counselor.

Counselors also have to be trustworthy in terms of keeping confidences, because everybody knows everybody in rural communities. Dual relationships

interfere with good treatment and are ethically dangerous, though sometimes unavoidable, in rural communities. There may be a clinical half-life to a professional living in a small community.

## SCHOOL COUNSELING

---

In addition to their typical developmental issues, children and adolescents currently face many challenges to their healthy growth and development. According to the American School Counselor Association (ASCA), school counselors accept responsibility for helping all children and adolescents make age- or grade- appropriate progress in their personal, social, educational, and career development. School counselors also assist children and adolescents who present different degrees of need for special help in these areas—needing help with developmental issues *and* issues inherent in their own circumstances. These special issues may arise when children or adolescents are unable to accomplish developmental tasks or when circumstantial obstacles interfere with their progress. A familiar example of the former is the adolescent who prefers to spend time with friends rather than attend class. A familiar example of the latter is the child who cannot concentrate on schoolwork due to troubles at home. School counselors work with children and adolescents who are situated along the entire mental health–mental illness spectrum and from different cultures. School counselors also work with students’ parents, teachers, and administrators.

### **Comprehensive School Guidance and Counseling Programs**

In rising to the challenges of serving large caseloads of clients—the ASCA recommended ratio is 250:1; the current range across the states is 222:1 to 1301:1—with

developmental and circumstantial issues, school counseling professionals have reached consensus about the means for delivering school counseling to students. Initially conceptualized by Gysbers and Moore, the comprehensive school guidance and counseling program model is endorsed in the *ASCA National Model* and in the models of a majority of the states.

The four elements of a comprehensive school guidance and counseling program are those of content; organizational framework; resources; and development, management, and accountability. The content element describes standards for student competency development. To guide meaningful practice, competencies must be specified for each grade level or grade grouping. There are national content standards published by ASCA. Many state and local school district models include content competencies appropriate to their schools’ missions and communities.

The organizational framework element describes structure, activities, and time parameters that support program delivery. The structural components present the definition of, the assumptions behind, and the rationale for the program and its implementation design. The program activity components define activities as guidance curriculum, individual student planning, responsive services, or system support. The time portion of the element describes examples (as in the *National Model* and the text), or recommendations, guidelines, or rules (as in state models) for appropriations of school counselor time for each of the program activity components.

The resources element describes the personnel and financial and political resources needed to fully implement a program. The development, management, and

accountability element describes a systematic process for schools and school districts to use to tailor their programs to best assist their students' development that make wisest use of the allocated resources. The five phases of this process are planning, designing, implementing, evaluating, and enhancing.

### **Six Changes for the 21st Century**

Even in states and school districts with well-described programs, and even with research that documents the value added to students' development within fully implemented programs, program implementation is uneven at the present time. A legitimate goal on behalf of equitable services for all students is to have fully implemented programs in all schools. This entry identifies six goals for changes that may lead more schools to fuller implementation of their programs:

1. Clarity of school counselor professional identity
2. Meaningful school-based leadership for school counselors
3. Multicultural competence of school counselors
4. Relevant school counselor education and training
5. Use of technology for program and counselor accountability and evaluation
6. Fuller understanding and support for guidance and counseling by noncounselors

Each of these was the target of recent work, and the successes of these early efforts suggest that they are feasible improvements for all to consider.

#### ***School Counselor Professional Identity***

To fully implement comprehensive school guidance and counseling programs, school counselors need to be clear about their professional identity. The program establishes the framework for an appropriate job description for school counselors and the basis for school counselors' professional identity. Historically, there has been debate about whether school counselors are counselors *or* educators. School counselors are both. Their responsibilities include educator tasks, such as teaching (guidance curriculum) and guiding individual student planning, *and* counselor tasks, such as individual and small group counseling and

consulting (responsive services). Program development and management, collaborating with colleagues and administrators, and reaching out to the community (system support) are tasks done by both counselors and educators.

While the program model is helping change the situation, school counselors still spend a disproportionate amount of time doing nonguidance tasks (e.g., administrative, clerical, instructional, or student supervision duties). With clear standards for the program, for school counselor competence, and for ethical behaviors and values, counselors will continue to replace these tasks with those that apply their professional competence. Additionally, having one vision for the program and school counselors' jobs provides a common language for school counselors across the United States. Communication and affiliation among school counselors based on a shared identity strengthens that identity.

#### ***School-Based Leadership***

To fully implement comprehensive school guidance and counseling programs, school counselors need leadership. To maintain a meaningful program, leadership for its development and management is a continuous responsibility. To encourage their ongoing professional development, school counselors need administrative and clinical supervision by school counseling professionals.

At the school level, leadership of the majority of school counselors is provided by school principals. While they may be effective educational leaders, most school principals do not have expertise in school counseling. Some school counselors have leadership qualities, but they do not have training in leadership for program and staff development. At this time there is no identity for building-level or district-level school counselor leaders: There is no established job title and only a minimal amount of professional literature and research. Standards need to be established for their work. School counselor leaders need to be educated, trained, and certified to meet these standards.

#### ***Multicultural Competence***

To fully implement comprehensive school guidance and counseling programs, school counselors need to respond effectively to the diverse students,

parents, and educators whose cultural roots or backgrounds are different from theirs. They must be multiculturally competent. In 1998 Sue, Arredondo, and McDavis defined multicultural competence for professional counselors. The profession continues to produce much research-based information to inform counselors regarding most effective ways of assisting people in their own cultural context.

Multiculturally competent individuals are always works in progress. Education and training to become cross-culturally proficient begins in counselor preservice education and should continue in ongoing inservice training and other professional development activities for practicing school counselors. As with the counseling field as a whole, school counselors are predominantly from White, middle-class backgrounds. A counseling staff in a school should include representatives from the cultures of the communities the school serves.

Multicultural competence is also essential to enabling school counselors to provide equitable services to their students. School counselors must be competent at using culturally appropriate counseling interventions. When program priorities are established, different needs of different groups of students should be considered and responded to. Cultural differences should not be the basis of discrimination—either overt or covert. In addition, school counselors help students develop multicultural competence. Multiculturally competent school counselors must also advocate for culturally different students and collaborate with their educator colleagues to help schools be more responsive to their communities.

### ***School Counselor Education and Training***

To fully implement comprehensive school guidance and counseling programs, school counselors need education programs that provide them with the knowledge and skills they need to carry out the program. Currently, there is a shortage of counselor educators who have practiced as school counselors or who have worked in elementary or secondary schools. Doctoral programs in counselor education are not readily accessible to school counselors. Incentives are not typically offered by school districts to encourage doctoral level study, and school counselors must leave their jobs to attend a university full time.

In reality, education continues across the span of a school counselor's career. Counselor educators in

partnership with local schools and districts could assist in inducting new school counselors into actual school counseling practice and in providing ongoing professional development experiences for all school counselors. A majority of states have continuing education requirements for certificate renewal. Counselor educators may be the best resources for providing multicultural and technological competence development. They are also well positioned to develop and provide the leadership training needed by school counselor administrative and clinical supervisors.

### ***Use of Technology***

To fully implement comprehensive programs, school counselors need to use technology to meet expectations for accountability and evaluation. They need to be accountable for the efficient use of their resources (including their time) and to evaluate their effectiveness in program delivery (student results, program completeness). Technology facilitates data collection, management, interpretation, and reporting.

New counselors are more technologically literate than counselors trained several years ago. In-service training, consulting, and mentoring are required to help those who may be uncomfortable with using numbers, data, and technology. In most schools, there is access to the computer equipment and software programs needed (e.g., word processing, spreadsheets, presentation, databases, and the Internet). Many schools have technology specialists available to help counselors. Developers need to create accountability and evaluation models for school counselors that are practical and simple to use.

### ***Understanding and Support From Noncounselors***

To fully implement comprehensive school programs, school counselors need to continue to garner support for the program and the profession from principals, parents, and policymakers. Support is generated when noncounselors understand the value and purposes of the work. In tailoring the program model to their schools and districts, school counselors are urged, and mandated in some states, to collaborate with school staff, parents, and community representatives. When multidisciplinary groups are part of the design team, they are more apt to understand and believe in the program and its value. Counselors

themselves need to be open to receiving input as to desired program improvements. Accountability and evaluation data can be used to show the value to students of the program. When the program structure, the professionalism of school counselors, and the resultant benefits for students are clear, policymakers (e.g., school board members and legislators) are able to listen to, understand, and be supportive of school counselors' work.

## SCHOOL PSYCHOLOGY

---

The profession of school psychology developed from the need of school personnel to classify and manage children with educational and behavioral problems. The purpose of this entry is to describe the growth of school psychology and to illustrate how school psychologists are uniquely trained to fulfill many roles, both within and outside of the school setting. School psychologists display skills and abilities that can be successfully applied toward meeting the future needs of a diverse society.

## History and Development

### *Lightner Witmer*

Lightner Witmer, considered the father of school and clinical psychology, was probably the earliest practitioner of school psychology. In 1888, Witmer started his career teaching English and history at a preparatory school, where he was intrigued by students who had difficulties learning despite being motivated and bright. This may have piqued his interest in the empirical study of learning, which characterized much of his future work. Witmer then pursued graduate study at the University of Pennsylvania, and later he led James Cattell's psychology laboratory, primarily to study children who had learning problems. Through his seminal work in the laboratory, Witmer provided the foundation for what has come to be known as the scientist-practitioner model.

### *The Scientist-Practitioner Model*

The scientist-practitioner model emphasizes both science and practice, so that one area informs the other, and the practice of professional psychologists represents an integration of science with professional skills. Using this approach, Witmer worked with children who displayed school-related difficulties. Specifically, one struggled with the English language, and one had been labeled a chronic bad speller. From these descriptions, these children would most probably be diagnosed today as having a learning disability. In a systematic manner, Witmer searched the literature and found that psychology had not investigated causes or treatments for these disorders. Witmer argued that there were no principles for him to follow, and thus, he had to scientifically study these children before developing appropriate interventions. In a paper presented at the Annual Meeting of the American Psychological Association (APA), Witmer proposed a plan involving the training of students for a new profession: psychological experts who would work with the schools and hospitals to help students who had difficulties.

### *Historical Conferences*

At the present time, the majority of school psychology training programs embrace the scientist-practitioner model of training articulated by Witmer. This model was recommended in 1949 at the Boulder

conference, which was held to examine the training of professional psychologists. The shortage of trained psychologists to serve school-age children after World War II led to the Thayer Conference in 1954. The purpose of the Thayer Conference was to address the roles, functions, and training specific to school psychologists. The Vail conference in 1973 led to advocacy of a professionally oriented model of training, emphasizing applied coursework and culminating in the awarding of the doctor of psychology degree (Psy.D.). This training model focused on the delivery of professional services, and although not many school psychology programs currently offer this degree, there has been growing interest in moving toward applied practice. The majority of school psychology programs offer degrees at the master's, educational specialist, or doctoral level.

### **Levels of Training**

Specialist and master's degree programs in school psychology typically include 3 years of full-time graduate study (including an internship). Most doctoral programs require 2 additional years of education. The specialist- and master's-level degrees appear to be the most cost-effective training option, because school psychologists can practice at the predoctoral level. Although specialist- or master's-level training seems to be sufficient for practice within the schools, additional competencies are provided by doctoral training and may be more important to successful practice in nonschool or clinical settings. School psychology programs of various levels may be accredited by the National Association of School Psychologists/National Council for Accreditation of Teacher Education or by the APA.

## **Training**

### **NASP/NCATE Accreditation and Standards**

The nationally recognized accrediting body for education specialties is the National Association of School Psychologists/National Council for Accreditation of Teacher Education (NASP/NCATE). These organizations accredit teacher education programs as well as educational training programs (e.g., school psychology). For member institutions of NASP/NCATE, the six training standards of NASP are enforced through the accreditation review process.

*Standard I, Values as a Program Foundation*, represents a commitment to understanding and responding to human diversity. *Standard II, Knowledge Base, Training Philosophy, Goals, and Objectives*, stresses the need for an integrated and sequential program of study and practice. *Standard III, Practica*, stresses the centrality of supervised practice and the nature of its training activities as preparatory to the internship. An internship of 1 academic year is specified in *Standard IV* along with specific features that should characterize this component of training. A systematic evaluation plan is encouraged in *Standard V, Performance-Based Program Accountability*, which emphasizes measures of program elements and student outcomes. *Standard VI, Program Level and Structural Requirements*, differentiates specialist-level programs from doctoral-level programs in total credit hours and includes evaluation of graduates and programs.

### **APA Doctoral Accreditation and Standards**

Recognized nationally as the accrediting body for doctoral psychology programs in professional psychology, the American Psychological Association (APA) accredits those programs that self-declare a specialization in primarily clinical, counseling, and school psychology. The APA accreditation model is based on three principles that rest at the core of the profession. First, doctoral education and training is conceptualized as being broad and professional in preparation for entry-level professional psychology practice. Second, the science and practice knowledge base should be relied on by the training programs in the preparation of professional psychologists. Third, considerable latitude is offered each program to define its own philosophy and model of training.

Although no APA school psychology training standards exist per se, APA has specified that APA-accredited school psychology programs must meet the definition of a school psychology program provided by APA Specialty Guidelines for the Delivery of Services by School Psychologists. In addition to being primarily psychological in nature and recognized by the institution as a school psychology program with an identifiable body of students, there must be an identifiable psychology faculty and a psychologist responsible for the program. As mentioned previously, doctoral-level school psychologists usually have expanded training that widens the scope of their skills and understanding, allowing them to serve more

diverse roles in society, including practice in schools and other clinical settings such as hospitals.

## Roles of School Psychologists

Although a wide variety of functions have been suggested as appropriate for the school psychologist, psychological and educational assessment of children for placement in special education programs has been school psychologists' most visible role. In earlier decades, this function was primarily psychometric, although the conceptualization and practice of assessment has broadened recently due to legislative initiatives and changing problem-solving strategies. Three conferences on the promise of school psychology (Spring Hill, Olympia, Futures) helped to broaden the role of psychologists in the schools, reducing a focus on assessment and establishing intervention (and sometimes prevention) as necessary activities for school psychologists.

Given this focus on intervention, new models have been developed such as the Response to Intervention (RTI) model that permits the delivery of services that are more closely related to the psychological and educational needs of children. Instead of focusing on psychometric testing to determine eligibility, RTI emphasizes evidence-based interventions guided by a functional analysis of behavior, which lead to the implementation of effective interventions in academic, social-behavioral, and psychological domains.

School psychologists currently work as members of teams in which a more comprehensive approach to service delivery is taken. School psychologists assist teachers by conducting individual and group interventions for students with academic, emotional, or behavioral problems. School psychologists work with teachers in more direct ways through individualized consultation. Consultation is one means by which school psychologists "give psychology away" to nonpsychologists. The goal of consultation is to help clients (usually students) indirectly through engaging in a problem-solving process with the consultee (usually teachers or parents).

By working directly with parents and community members, school psychologists act as change agents and accept leadership roles for enhancing positive relationships between schools, families, and the community. School psychologists are in an ideal position to facilitate initiatives surrounding planning, implementing, and evaluating strategies for building constructive relationships between the home, school, and

community. To help society, school psychologists may serve in medical settings, businesses, neurological settings, residential treatment facilities, and private practice. By involving students, families, and the community, school psychologists can lead initiatives to promote safe schools with positive climates free of drugs, violence, and fear.

## The Future of School Psychology

School psychologists are exceptionally well trained to apply skills and knowledge in various functions both in and out of the schools. Although school psychologists may earn an accredited degree at the master's, specialist, or doctoral level, the training afforded by doctoral programs enables school psychologists to perform a broader range of functions. With extensive training, school psychologists have the knowledge, skills, and dispositions needed to meet the changing needs of children, youth, teachers, and families in our problem-saturated society.

---

## SCHOOL REFUSAL BEHAVIOR

---

School refusal behavior refers to child-motivated refusal to attend school or difficulties remaining in classes for an entire day. The behavior applies to 5- to 17-year-old children who are completely absent from school, who skip classes or certain sections of a school day, who are chronically tardy to school, or who attend school under intense duress that precipitates pleas for future nonattendance. Many youths display a fluctuating course of school refusal behavior that may include full absence one day, partial absence another day, and tardiness or a skipped class still another day.

Acute school refusal behavior may be defined as absenteeism lasting less than 1 calendar year, whereas chronic school refusal behavior may be defined as absenteeism persisting for more than 1 calendar year. In general, school refusal behavior is considered problematic if it lasts at least 2 weeks or significantly interferes with daily functioning. School refusal behavior is distinguished from school withdrawal, which refers to a parent who deliberately keeps a child home from school. In addition, school refusal behavior is not meant to include youths who fail to attend school because of extenuating circumstances such as homelessness or maltreatment.

### Historical Overview

Many terms have been applied to school refusal behavior, including problematic absenteeism, truancy, psychoneurotic truancy, school phobia, and separation anxiety. Each term describes a subset of youths with school refusal behavior. For example, truancy refers to illegal absenteeism in which a child misses school without parental knowledge. Other terms describe

youths with anxiety-related conditions such as dread (psychoneurotic truancy), fear (school phobia), and worry about separation (separation anxiety). The term “school refusal” is often used to refer to anxiety-based absenteeism as well. Many of these terms have been poorly defined, however, and are used in various ways by educators, clinicians, and researchers. The umbrella term “school refusal behavior” has been proposed to cover all youths with problematic absenteeism, whether anxiety-related or not, and to provide consensus for educators, clinicians, and researchers.

### Characteristics of Youths With School Refusal Behavior

School refusal behavior affects an estimated 5% to 28% of school-age children. According to the National Center for Health Statistics, 0.9% of children did not attend school at all in 2003. Furthermore, 5.4% of youths missed 11 or more days of school, 11.3% missed 6 to 10 days of school, and 28.1% missed 3 to 5 days of school in 2003. The number of absences due specifically to school refusal behavior, however, is unclear.

Peak age of onset of school refusal behavior is 10 to 13 years, though many youths entering a school building for the first time appear especially vulnerable. School refusal behavior is equally common among boys and girls and across sociocultural groups, though school dropout rates tend to be higher among Hispanics than among the general population. School refusal behavior is generally associated with adequate academic achievement up to the onset of absenteeism.

A hallmark of youths with school refusal behavior is symptom heterogeneity. The clinical picture of youths who refuse school is quite varied and includes many internalizing (covert) and externalizing (overt) symptoms. Common internalizing symptoms include general and social anxiety, depression, fatigue, somatic complaints, fear, worry, and self-consciousness. More specifically, common somatic complaints include headaches, stomachaches, abdominal pain, nausea, vomiting, diarrhea, trembling, and heart palpitations. Common externalizing symptoms include noncompliance and defiance, refusal to move, running away from school or home, aggression, and acting-out behaviors in school in an attempt to be sent home.

Most children with school refusal behavior display a complicated diagnostic picture as well. The most common diagnoses associated with school refusal behavior are anxiety-related conditions, such as separation

anxiety disorder, generalized anxiety disorder, and social anxiety disorder, and depressive-related conditions such as major depression and dysthymia. However, about one third of this population meets criteria for no mental disorder.

In the short term, school absenteeism causes substantial stress for a child and family members and can lead to social alienation, declining grades, family conflict, and financial and legal troubles. In the long term, chronic absenteeism is a risk factor for juvenile delinquency and school dropout. Longitudinal studies of youths with chronic absenteeism also reveal increased risk for social, occupational, economic, marital, and psychiatric problems in adulthood.

### Functional Model

Many systems have been designed to classify youths with school refusal behavior with respect to various forms of internalizing and externalizing behavior. Examples include general clinical, diagnostic, and empirical/statistical methods of classification. These systems demonstrate only mixed success at categorizing large percentages of youths who refuse school because of the heterogeneity of symptoms for these children. An alternative functional model for classifying youths with school refusal behavior along the major reasons or reinforcers of absenteeism has gleaned substantial empirical support. These functions include avoidance of stimuli that provoke a general sense of negative affectivity (symptoms of anxiety and depression), escape from aversive social or evaluative situations, pursuit of attention from significant others, and pursuit of tangible rewards outside of school.

The first two functional conditions refer to youths who refuse school for negative reinforcement, or to avoid or escape something aversive at school. The latter two functional conditions refer to youths who refuse school for positive reinforcement, or to pursue rewards outside of school. Many youths refuse school as well for a combination of these functions. The functional model may serve as the basis for a comprehensive assessment and treatment process.

### Assessment

Assessing youths with school refusal behavior typically involves structured diagnostic interviews, child self-report measures of internalizing symptoms, parent- and

teacher-based measures of internalizing and externalizing behaviors, behavioral observation, and examination of medical, academic, and attendance records. In addition, the assessment process should focus on the function of a child's school refusal behavior. Medical assessment of somatic complaints and related physical conditions is common as well. Assessment is best conducted as a multidisciplinary process that involves parents, children, peers, school personnel, and health and mental health care professionals.

### Treatment

Treatment of youths with school refusal behavior often involves an emphasis on restoring full-time attendance and addressing anxiety and other mental conditions associated with the behavior. As such, treatment usually includes child-, parent-, and family-focused techniques. Child-based techniques include psychoeducation about the nature of anxiety, somatic control exercises to ease physical symptoms of anxiety (e.g., relaxation training, breathing retraining), cognitive restructuring to challenge and change irrational thoughts, and exposure-based practices to ease a child back into school. This last technique is often done by systematically adding hours, periods, or classes to a child's school day. The general goal of these child-based techniques is to reduce distress associated with school and increase school attendance on a gradual basis.

Parent-based techniques include restructuring parent commands toward brevity and clarity, ignoring a child's simple inappropriate behaviors (e.g., morning dawdling), establishing fixed routines in the morning and evening, establishing rewards and punishments for attendance and nonattendance, reducing excessive reassurance-seeking behavior, and engaging in forced school attendance under certain conditions. The general goal of these parent-based techniques is to reduce attention-seeking child behaviors and re-establish parental control via contingency management.

Family-based techniques for school refusal behavior include negotiating and designing written contracts, escorting youth to school and classes, communication skills training for family members, and peer refusal skills training to help youths decline peers' suggestions to miss school. The goal of these family techniques is to increase incentives for school attendance and decrease incentives for nonattendance while improving family problem-solving skills.

Treatment for school refusal behavior may also involve medication, monitoring of school attendance on a daily basis, increased parental and school supervision, resolution of peer- and teacher-related conflicts, social skills training, behavioral activation, and development and modification of 504 and individualized educational plans. Use of daily attendance journals and increased participation of the child in school-based extracurricular activities is recommended as well. In addition, ongoing consultation with a child's pediatrician, school guidance counselor, school psychologist, and teachers is often crucial to resolve a particular case of school refusal behavior. Relapse prevention following resumption of full-time attendance is also necessary in many cases.

## SCIENTIST–PRACTITIONER MODEL OF TRAINING

The integration of professional practice with scientific thinking and research has been a defining characteristic of professional psychology since its inception, although it was first formally articulated as part of the doctoral training model at the Boulder conference in 1949. The scientist–practitioner model has been central to counseling psychology identity and training since its endorsement at the Greyston conference in 1964 and reaffirmation at the Georgia conference in 1987. In 1990, The National Conference on Scientist–Practitioner Education and Training for the Professional Practice of Psychology reaffirmed the scientist–practitioner model as a true integration of science and practice in which each activity continually informs the other. In spite of the professional consensus that psychologists should approach their practice scientifically and base their practice activities on scientific evidence, there is an equally strong consensus that counseling psychology (and other areas of professional psychology) have fallen short of realizing the scientist–practitioner model.

Now, more than ever, a true integration of science and practice is needed. Changes in the healthcare system, increasingly demanding managed care entities, and competition with other mental health professions have created greater demand for proof that psychologists' activities and interventions are effective. Traditional fee-for-service psychological activities are being replaced by activities such as program development and administration, training and supervision of other mental health professionals, evaluating the effectiveness of behavioral healthcare and educational programs, and influencing public policy.

### History and Definitions

The scientist–practitioner model, also known as the Boulder model, was developed at the Conference on Graduate Education in Clinical Psychology held at the University of Colorado at Boulder in 1949. This 2-week-long conference was the first national meeting held to discuss standards for doctoral training in psychology in the United States. Conference attendees concluded that psychologists should provide both professional services and research contributions. Furthermore, the 1949 Boulder conference attendees

endorsed a wide range of psychological practice, including work with more normal clientele and traditional counseling psychology realms such as vocational counseling. In 1954, Pepinsky and Pepinsky further articulated the activities of the counselor-as-scientist. As early as 1961, however, psychologists began to recognize and be concerned about the scientist–practitioner split.

### Current Status

Hayes and colleagues, in perhaps the most comprehensive consideration to date of how psychologists enact the scientist–practitioner model, described an integrated model of science-based practice in managed behavioral health care, which includes psychologists' contributions to community-level prevention and health development services, practice guidelines and triage to services provided by different levels of practitioners, evaluation and outcome assessment, and the development of new treatments from innovation through program evaluation and efficacy testing to dissemination. Models such as this show how psychologists can integrate science and practice in a wide variety of ways in the full range of settings in which they work. However, there are still barriers to overcome as counseling psychology moves forward toward science–practice integration.

### Training Issues

Many members of the original Boulder delegation questioned whether all graduate students could be trained to do both science and practice. Not only has such integrated training in science and practice been impossible to date, but it has been shown to be unrealistic to expect all psychologists to be both skilled practitioners and productive researchers. The successful conduct of research and practice requires different styles and skills, and individuals seeking a career in professional psychology self-select into professional activities that reflect their unique personalities, aptitudes, and interests. Because of fundamental differences in the demands of science and practice, there are few truly integrated scientist–practitioners, in any setting, to serve as role models. The reality of graduate training in psychology is that science and practice activities are typically separated, with the majority of scientific training and mentoring occurring in classroom settings with faculty and the majority of practice training and mentoring occurring in external

practicum settings with psychologists who identify as practitioners.

A number of counseling psychologists have attempted to build more systematic scientist–practitioner attitudes and behaviors into counseling psychology training. Efforts have been made to develop models to incorporate scientific thinking and methods (e.g., hypothesis testing) into practice activities such as assessment. Changes have been suggested to the practicum training sequence to include systematic data collection using single-case or time series research methods and empirically based rationales for specific treatment interventions. Other suggested additions to a counseling psychology program curriculum to increase scientific activity include an ongoing research practicum, a qualitative methods course, and an advanced research design course specific to counseling psychology. To date, efforts to increase scientist–practitioner integration have been typically focused on increasing the scientific thinking and activity of practice-oriented students, and little attention has been given to increasing the practice orientation of researchers.

### Technological Issues

One of the greatest barriers to true integration of science and practice is the currently available research technology. Randomized clinical trials (RCTs), considered the gold standard in psychotherapy research, rarely yield information that practitioners can use. Current psychotherapy research methods, typically focused on treatment efficacy, have been used to identify treatments that work (i.e., yield outcomes better than no treatment). However, psychotherapy research methods have not consistently distinguished particular therapeutic approaches as more or less effective than others, making those methods of little utility to practitioners in terms of their professional decision making or accountability. Furthermore, RCT designs have relied upon strategies such as random assignment, uniform diagnostic groups, and treatment manualization, making them difficult to generalize to the real-world activities of practitioners who deal with complex cases and culturally diverse clients.

There have been recommendations for increased focus on effectiveness research, testing psychological treatments in real-world settings with real clients, but such effectiveness research initiatives are just beginning to yield methodological and outcome developments. Effectiveness research efforts are quite

promising, and effective interventions and therapists are being identified. However, conducting psychotherapy research in real-world practice settings poses a number of unique logistical, ethical, and methodological challenges.

One of the greatest challenges inherent in psychotherapy science and in the scientist–practitioner model is the need to develop methods that adequately tap into the scientific and therapeutic activities of practitioners. At this point, little is understood about the counselor-as-scientist (i.e., the processes that drive the moment-by-moment decisions of practitioners). The success of the scientist–practitioner model depends on counseling psychology’s ability not only to address questions derived from practice but also to learn from the scientific process of practitioners.

### Evidence-Based Practice

The newest development in science–practice integration is evidence-based practice. Evidence-based practice was originally defined as the systematic use of research evidence to make practice decisions. More recently, evidence-based practice has been more broadly conceptualized to include a general attitude toward gathering and using evidence, taking evidence from a variety of methods and sources, and using a wider range of information in making professional decisions. It has been argued that evidence-based practice can be a bridge over the scientist–practitioner split, as psychologists all begin to consider themselves to be evidence-based *practitioners*, rather than scientists *or* practitioners.

The American Psychological Association convened a panel of prominent practitioners and psychotherapy scientists to define evidence-based practice. The task force, in their 2005 policy statement, defined evidence-based practice in the most comprehensive manner to date—from any profession. Evidence-based practice demands that treatment decisions are based on the best available research evidence, on clinical expertise, and on client characteristics, culture, and preferences. Furthermore, the task force called for a broader conception of evidence (e.g., clinical observation, case studies, ethnographic research, process-outcome studies), for efforts to understand and facilitate the clinical expertise processes (e.g., studying clinician practices, developing measures clinicians can use, providing real-time client progress feedback), and for greater attention to the influence of client characteristics (e.g., testing tailored treatments,

applications to populations other than majority populations, improving psychologists’ competence with diverse clients, identifying models of client preference-based treatment decision making). Evidence-based practice, in this comprehensive formulation, may be the avenue by which psychologists come to embody the science–practice integration envisioned by the Boulder and Greyston delegates more than a half-century ago.

## SEXUAL VIOLENCE AND COERCION

---

The Centers for Disease Control and Prevention (CDC) have developed uniform, nonlegal definitions for sexual violence and related terms in an effort to

standardize the reporting and study of these crimes. Inclusionary criteria are broad and divide these crimes into five categories, which include (1) completed nonconsensual sex acts, including penetration, to any degree, of a genital opening or anus, and sodomy, (2) attempted nonconsensual sex acts, (3) abusive sexual contact, including any intentional touching that could be construed as sexual, (4) noncontact sexual abuse, including such acts as voyeurism, harassment, and pornography, and (5) sexual violence, unspecified type. Contact is considered nonconsensual if the victim says no at any time; participates because of pressure, coercion, or intimidation; or is unable to consent because of age, intoxication, illness, being asleep, or any other disabling condition.

Under a grant funded through the CDC and the National Institute of Justice, the National Violence Against Women Survey (NVAWS) found that 1 in 6 women and 1 in 33 men reported being victims of attempted or completed rape in their lifetimes. Alarming, 54% of female victims reported being raped before age 18. Rape is often accompanied by other forms of physical assault, including beating, choking, kicking, and use of a weapon, to name a few. In contradiction to the stereotypical portrayal of the rapist as a stranger, in most cases the perpetrator is a current or former intimate partner, an acquaintance, or a relative. A majority of children who experience sexual violence or coercion without penetration or sodomy also know and trust their perpetrators. Estimates of childhood sexual abuse vary, but range from a low of 6% for females and 3% for males to a high of 62% for females and 31% for males.

While the majority of victims of sexual assault are female, the majority of perpetrators are male, regardless of the sex of the victim. Sexual assault and coercion are crimes of violence and abuse of power, not of sexual desire. The intention of the perpetrator is to humiliate and to control the victim, not to obtain sexual gratification from or intimacy with another person.

Survivors of sexual violence are likely to face a number of psychological challenges in their attempts to cope with and adapt to their victimization and their lack of real or perceived safety. Feelings of shame, doubt, helplessness, hopelessness, unreality, fear, and anger, to name a few, are common, and while reactions vary in relation to age and psychological resources, the experience of sexual assault has strong negative consequences for most victims. Unfortunately, it appears that few victims of sexual violence, including those who sustain physical injury, seek treatment for their difficulties.

Without treatment, individuals who have been traumatized tend to live traumatizing lives, and sexual violence tends to recur in the lives of individuals who have previously been victims, serving to confirm their lack of safety and leading to more psychological distress.

Initial concerns in the treatment of survivors of sexual violence include provision of emotional and physical safety, both in and out of therapy, monitoring for suicidal ideation, and developing a strong, trusting therapeutic relationship. Victims of rape have high rates of attempted suicide, and often experience questionable support. Unfortunately, rape and sexual abuse appear to be among the few violent crimes for which the victim is perceived as, and often feels, partially responsible. It is important to address the issues of shame surrounding experiences of sexual violence and to help victims understand that they were not at fault. Personal safety issues should be addressed in the context of what can be done to help keep the individual safe now and in the future, with careful assessment of the survivor's reaction to these offerings. It is essential to balance fostering a sense of control with engaging in strategies that help survivors move from an intellectual understanding of the perpetrator's responsibility for the crime to an emotional sense of their own innocence. It can be dangerous to cultivate an attitude that "if only I had done something different, this would not have happened to me," as it tends to feed the victim's sense of personal responsibility for a violent act that was perpetrated against him or her. Because treatment of difficulties related to sexual violence and coercion is a specialized area, it is important that therapists choosing to treat survivors gain the required competencies.

Given the nature of our society's attitude toward sexual violence, seeking closure through legal channels can be a disappointing and degrading process, as it is estimated that a very small percentage of rapists are incarcerated due to prosecution. It is important that therapists who treat victims of these crimes have a broad understanding of the statistics and literature related to the legal issues involved. Survivors of sexual violence should be given as much control over their decisions as possible while taking into consideration all relevant information.

## SLEEP DISORDERS

---

“Sleep tight and sweet dreams” used to be the phrase used when bidding a family member good night. Unfortunately, a significant number of individuals have difficulty either falling asleep or staying asleep for the 7 to 8 hours recommended by the National Institutes of Health. (However, this is a general recommendation and varies by both age and the individual. For example, infants need on average about 16 hours of sleep per day, teenagers approximately 9 hours, adults the 7 to 8 recommended hours, with older adults requiring about the same as younger adults or up to 9 hours sleep.) Between 50 million and 70 million individuals are impacted by sleep-related problems. This is a serious issue, as sleep is a neurobiological need. The ultimate result of sustained sleep loss can be death. Not only is a significant percentage of the U.S. population impacted by sleep disorders, sleep has also become a big business; there are over 2,800 U.S.-based sleep centers. Sleep center revenue is expected to climb to \$4.4 billion by the year 2011, and this does not account for the estimated \$3 billion in revenue to pharmaceutical companies from the 43 million prescriptions written annually for sleep disorders.

The National Institutes of Health has classified over 80 types of sleep disorders. The *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision (DSM-IV-TR)* organizes sleep disorders into four major categories: primary sleep

disorders, sleep disorder related to another mental disorder, sleep disorder due to a general medical condition, and substance-induced sleep disorder. Included within these categories causing sleep disturbance are psychiatric illnesses like depression and posttraumatic stress disorder (PTSD); medical or biological contributors like hypertension and coronary artery disease; situational contributors of shift work, poor environment, and jet lag; medicine or drugs, which includes alcohol, stimulants, and narcotics; and numerous others like sleep apnea, genetics, ethnicity, and the aging process. It appears from all the data that the United States is becoming a sleep-deprived nation. The good news is that there is rapidly growing attention to this problem, as more than \$110 million has been invested in sleep related research since 1996.

## Definition of Sleep Disorder

An all-encompassing definition of a sleep disorder is difficult due to the broad categories and significant number of sleep disorders within each category. However, to establish some frame of reference, following are examples of major sleep disorders as defined by *DSM-IV-TR*:

*Primary insomnia*: “Difficulty initiating or maintaining sleep or of a nonrestorative sleep that lasts for at least 1 month (Criterion A) and caused clinically significant distress or impairment in social, occupational, or other important areas of functioning (Criterion B).” This is the most common of the sleep disorders.

*Breathing-related sleep disorder*: “Sleep disruption, leading to excessive sleepiness or, less commonly, to insomnia, that is judged to be due to abnormalities of ventilation during sleep (e.g., sleep apnea or central alveolar hypoventilation).”

*Circadian rhythm sleep disorder*: “Persistent or recurrent pattern of sleep disruption that results from altered function of the circadian timing system or from a mismatch between the individual’s endogenous circadian sleep-wake system and exogenous demands regarding the timing and duration of sleep.”

*Dyssomnia not otherwise specified* includes “complaints of clinically significant insomnia or hypersomnia that are attributable to environmental factors (e.g., noise, light, frequent interruptions); excessive sleepiness that is attributable to ongoing sleep deprivation;

‘Restless legs syndrome’ characterized by a desire to move the legs or arms, associated with uncomfortable sensations typically described as creeping, crawling, tingling, burning, or itching.”

The definitions continue for additional sleep disorders, including nightmare disorder, sleep terror disorder, sleepwalking disorder, sleep disorders related to another mental disorder, sleep disorder due to a general medical condition, and substance-induced sleep disorder.

### **The Impact of Sleep Disorder**

The list of negative impacts from sleep deprivation and disorders is lengthy. The impact can depend upon many factors, including gender; age differences; and situational factors like stress, loss of a loved one, or jet lag. There are the physical consequences like lowered attention and executive functions resulting in loss of productivity at work, and impaired learning and memory. An estimated 56,000 automobile crashes annually are related to driver drowsiness and fatigue. Other impacts are a weakened immune system, a link between brain damage and sleep apnea, the inhibition of aggression and negative consequences to overall mood, emotional impacts such as the correlation between depressive symptoms and prominent fatigue, and an overall impaired quality of life.

### **Treatment: Psychology Versus Pharmacology**

Focusing on insomnia as the most prevalent of sleep disorders, several treatments are effective, including pharmacology, cognitive-behavioral therapy, stimulus control therapy, biofeedback, and relaxation training. Cognitive-behavioral therapy (CBT) has been shown to be an effective treatment for insomnia. Comparisons between CBT, pharmacological therapy, and the combination of the two on treatment for insomnia suggests that medications and the combination of medication and CBT produced greater short-term effects, but CBT alone appears to have the greatest long-term effect on improving sleep disturbances.

### **Advancements and Research Results**

There is still much to investigate regarding sleep disorders, but much progress has been made. Several clock genes have been discovered that have a significant role

in mammalian circadian timing, and newly discovered neurotransmitter systems influence regulation of rapid eye movement (REM). Regarding molecular biological approaches, the hypocretin system has been found to have a role in narcolepsy and behavior control, and cell groups in the hypothalamus and neurochemical phenotypes of neurons are important to REM. Research is also exploring the genetic basis of sleep. Treatment of neurological disorders can cause sleep disorders. Epileptic seizures can place individuals at further risk for sleep disorders. An interesting observation relating to age and gender is that approximately 90% of the individuals impacted by REM behavior disorder (RBD) are male, and most are over 50 years old. Disruption of sleep has also been found with most psychiatric disorders. The same is true for substance abuse.

Conversely, chronic insomnia can put an individual at risk for development of psychiatric disorders. The expression of some genes for synaptic plasticity in children can be impacted by sleep loss. Researchers now better understand sleep and the environment, including the impact of light, temperature, noise, motion (bed partners), location, position, and sleeping surface. Researchers also understand that chronic sleep deprivation can lead to cognitive deficits, weakening of the immune system, weight gain, heart disease, diabetes, and if severe enough even death. From a gender perspective, changes in a woman’s biochemistry, like those associated with pregnancy or menopause, can cause sleep deprivation. Ethnicity is also a factor in sleep disorders. The risk of sleep-disordered breathing (SDB) is approximately twice as great in young African Americans as in Caucasians. Adults that are non-Caucasian are at almost twice the risk of insomnia, which also affects approximately one third of older adults.

Technology has brought new and fresh perspectives to researching sleep disorders over the last 5 years. These include functional neuroimaging technologies like positron emission tomography (PET), functional magnetic resonance imaging (fMRI), single photon emission computed tomography (SPECT), near-infrared optical imaging (NIR), and others that allow researchers to see the brain in new ways. Additionally, electroencephalographic (EEG) brain-mapping studies, combined with electrooculographic (EOG) and submental electromyographic signals (EMG), allow researchers to view the patterns of connectivity between brain regions and how the brain responds while performing specific tasks. They can

demonstrate how functionality and cognitive capacity are altered by sleep loss. The combination of pharmacology, technology, and ongoing research into biology, genetics, psychology, and biochemical makeup holds great promise for successful treatment of many of the categorized sleep disorders.

## SPECIALIZATION DESIGNATION

---

Professional psychology as a field includes rigorous training covering a broad range of competencies, often within the domain of a specified course of study such as clinical psychology, counseling psychology, school psychology, or another area. Due to a variety of factors, an increasing focus on competency-based training and recognition of specialty training, with accompanying

board certification in that specialty, has evolved within the field. As a result, more psychologists seek board certification as a means of demonstrating competency in a specific area of specialization.

Within professional psychology, specialty areas are defined areas of practice or service addressing specific problems and populations. Specialty practice requires advanced knowledge, skills, and attitudes that have been acquired in addition to the more broad, general knowledge and training that serves as a foundation for professional psychology.

Specialization may begin during graduate training, yet it continues well beyond completion of the doctoral degree program. It is following several years of graduate study, completion of internship, and postdoctoral training that one becomes eligible to sit for the Examination for the Professional Practice of Psychology (EPPP) leading to licensure for practice within the profession. In most jurisdictions, that licensure is granted as a generic license to practice within the scope of one's training. Thus, licensure as a psychologist, in and of itself, is not considered recognition of specialization. Recognition of specialty in a specific area of psychology is generally made through a board certification process, most often under the processes established and conducted by the American Board of Professional Psychology (ABPP).

### Entities Involved in the Evolution of Specialization and Specialty Designation

Several organizations, most related directly or indirectly in some fashion to the American Psychological Association (APA), have played some role in the genesis and evolution of specialization and specialty designation in professional psychology. Among these are APA entities such as the Committee on Accreditation (COA), the Council for the Recognition of Specialties and Proficiencies in Professional Psychology (CRSPPP), the Association of Predoctoral, Postdoctoral, and Internship Centers (APPIC), the Association of State and Provincial Psychology Boards (ASPPB), the National Register (NR), the Canadian National Register (CNR), the Canadian Psychological Association (CPA), and the Council of Credentialing Organizations in Professional Psychology (CCOPP). A focus on postdoctoral training within the APA and COA and the establishment of the CRSPPP significantly advanced progress in recognition of psychological

specialties during more recent years. The Interorganizational Council for Accreditation of Postdoctoral Programs in Psychology (IOC), composed of several of these bodies, existed from 1992 through 1997 and led to the establishment of the Council of Specialties (CoS) in professional psychology.

The CoS was initially established jointly by the APA and the American Board of Professional Psychology (ABPP) and has provided a working definition of specialty in professional psychology similar to that provided above. Historically, ABPP has generally been recognized as the primary organization that examines, credentials, and certifies professional psychologists; the CoS indicates recognition of ABPP as the *only* such organization.

### Graduate Education

In 1977, the National Conference on Education and Credentialing in Psychology established guidelines for defining a doctoral degree program in psychology. This conference served as the basis for eventual establishment of programs that became accredited by the APA. The joint efforts of the ASPPB and the NR have resulted in recognition of many programs that, although not APA-accredited, are deemed to meet sufficiently similar standards for the purposes of licensing and credentialing. Recognized as ASPPB/NR Designated Doctoral Programs, these programs can be found listed on the Web sites of the ASPPB and the NR. The course of study is for all practical purposes the same as that of an APA-accredited program, and these are often referred to as APA-equivalent programs.

To be so recognized, a graduate program must be clearly identified as a psychology program, be offered through a regionally accredited institution of higher education, be an integrated and organized sequence of study, have an identifiable and sufficient faculty to function adequately, include supervised practicum and internship training, and require a minimum of 3 academic years of full-time graduate study, among other items. The program must also require that students demonstrate competency in the areas of (1) scientific and professional ethics and standards; (2) research design and methodology; (3) statistics and psychometric theory; (4) biological bases of behavior, including physiological psychology and comparative psychology; (5) neuropsychology, sensation and perception, and psychopharmacology; (6) cognitive-affective bases of behavior, including learning, thinking, motivation,

and emotion; (7) social bases of behavior, including social psychology, group processes, organizational theory, and systems theory; and (8) individual differences, including personality theory, human development, and abnormal psychology. As well, the programs must include course requirements in specialty areas. This graduate academic training establishes what have become recognized as the foundational competencies within professional psychology, while further postdoctoral training and experience lead to establishment of the functional competencies.

### Specialty Recognition and Credentialing

#### *The American Board of Professional Psychology*

In the 1940s, the APA formed a committee to study credentialing psychologists. That committee led to the establishment of the American Board of Examiners in Professional Psychology (ABEPP) in 1947. It was recognized that although members of APA might belong to divisions of that organization that are more or less specialized, those divisions are interest groups and could not reasonably be presumed to represent their members as necessarily being specialists in the area. An inherent potential conflict of interest between protection of the public and advancing the interest of division members existed; thus, with support from the APA, the development and establishment of ABEPP as a separate entity proceeded.

Initially, ABEPP certified practitioners in areas it labeled clinical, personnel-industrial, and personnel-educational psychology. The latter two areas evolved into industrial/organization psychology (later becoming organizational and business consulting psychology) and counseling and guidance (later becoming counseling psychology).

The organization changed its name to the American Board of Professional Psychology (ABPP) in 1968. Additional specialty areas were added, until eventually it grew to include 13 specialty boards as of this writing. These are the following: child and adolescent psychology, clinical psychology, clinical health psychology, clinical neuropsychology, cognitive and behavioral psychology, counseling psychology, family psychology, forensic psychology, group psychology, organizational and business consulting psychology, psychoanalysis, rehabilitation psychology, and school psychology.

The original ABEPP organized with the express intention of certifying only the most advanced practitioners in a given area of specialization, believing that state psychological associations should be responsible for those less advanced. Over time, this focus led to concern among some that the organization was elitist and not representing the mainstream of psychological specialists. As well, the question of whether board certification is necessary continues, often with responses suggesting that although it may not be *necessary* to an *individual* now, it is *essential* to the growth of professional psychology in the long run.

Concomitant with a national pursuit of competency-based training throughout the educational and training years in psychology, the organization has evolved into the current ABPP, recognizing the need to examine and certify psychologists at a level of competency that is beyond that of generic licensure yet not limited to only the most elite. It is expected that, akin to individuals in medical specialty areas, most adequately trained psychologists would meet the criteria and be able to pass the ABPP examination in their area of specialty following the completion of appropriate residency training experience ranging from 2 to 5 years of postdoctoral training and experience.

### ***Becoming Credentialed In Counseling Psychology***

Recognition of competency in a specific psychological specialty entails multiple steps. All ABPP specialty boards have similar basic, or generic, requirements, with each specialty board having additional, specialty-specific criteria. A psychologist must undergo credentials review and licensure verification, submit practice samples for review, and pass an oral examination in the specialty area. Some ABPP specialty boards also include a written examination.

Specialty credentialing in counseling psychology is conducted by the American Board of Counseling Psychology (ABCP), a specialty board of the ABPP. Summary information about specialty credentialing through the ABCP is found below, while more details may be found at the board's Web site (<http://www.abpp.org>). The ABCP indicates that counseling psychologists engage in helping people with personal and interpersonal functioning by way of individual, group, and community interventions that deal with emotional, behavioral, vocational, and mental health issues. They may use preventive, developmental, and

remedial approaches in assessment, diagnosis, and treatment of psychopathology. They may engage in psychotherapy, assessment, teaching, research, supervision, and career counseling.

### **Credential Review and Licensure Verification**

ABPP conducts a review of the education and training experience(s) of a candidate. This is conducted at a *generic* level for all candidates, and it consists of verification of training in an APA-accredited or ASPPB/NR-designated doctoral program, verification of internship and postdoctoral experience, and verification of licensure. When these criteria are established as having been met, credentials are reviewed by the ABCP at a *specialty* level to determine that requirements for appropriate training and experience in the specialty area have also been satisfied. In counseling psychology, the specialty criteria that must be met are (1) completion of an acceptable internship program, (2) 1 year of postdoctoral supervision, and (3) 2 years of postlicense experience. Acceptable supervision is one-on-one, face-to-face weekly supervision. All applicants must submit a copy of their curriculum vitae or resume. Graduates of a counseling psychology program accredited by APA must provide endorsement from two psychologists, and graduates of any program other than an APA-accredited counseling psychology program must provide attestations of their functioning as a counseling psychologist from two psychologists.

### **Practice Sample Submission**

The ABCP requires that counseling psychologists submit a professional self-study (PSS) as well as a case study (CS). The PSS is a document that describes training and experiences that have led the psychologist to the specialization in counseling psychology, including a description of theoretical bases for practice and a description of the approach(es) the psychologist makes use of in assessment and intervention. The CS is intended to demonstrate the psychologist's competency in counseling psychology. It may be an individual case, group work, or another demonstration of competency and may be submitted in written form. (The use of a video of the psychologist's work may also be acceptable in some cases.) The PSS and CS are reviewed by board certified peers for evidence of adequate competency in the areas of assessment,

intervention, consultation, and other areas appropriate to the practice of counseling psychology. Once this submission is approved, the candidate is invited to participate in the oral examination phase of the board certification process.

### Oral Examination

The board uses an assessment center model to conduct oral examinations, wherein a candidate moves through several separate examination areas, each with a focus on a particular competency area. The oral examination is conducted over a morning and an afternoon and consists of five competency domains: (1) assessment, (2) intervention, (3) alternative interventions, (4) ethics, and (5) professional issues. The candidate interacts with different examiners during different phases of the examination.

The oral examination includes discussion of the PSS as well as the CS that were previously submitted during the practice sample phase of the process. Additionally, the candidate provides a videotape of an individual client session to the oral examination committee chair 30 days prior to the date of the candidate's oral examination. The criteria used to evaluate oral examination performance are the same for all candidates without regard to their years of postdoctoral experience. On successful completion of the oral examination phase, the counseling psychologist is awarded the ABPP diploma in counseling psychology.

### Future Importance

The importance of specialization within the field of professional psychology is growing. Becoming board certified through an organization such as ABPP can facilitate mobility, or a psychologist's ability to practice in different states. Many states recognize a psychologist who has attained the ABPP board certification as having met the criteria necessary for licensure in the state and require only that (for example) an examination on state-specific regulations be passed prior to granting a license for the practice of psychology in that state. Board certification also represents increased responsiveness to protection of the consumer public. Recent developments have included states working to restrict the use of the term *board certified* or *specialist* to those psychologists who have attained board certification through an organization recognized by the state licensing

body. It is anticipated that specialization and appropriate credentialing of specialists will continue to become more of the norm and expectation within the field of psychology.

## STRESS-RELATED DISORDERS

---

There is a lack of consensus on how to best define the concept of stress. Concerns related to the scientific status of the construct have led some authors to suggest that it be abandoned altogether or restricted to nontechnical usage. Even at the level of physiology, the mechanisms involved in a stress response cannot be adequately differentiated from anxiety or depression. Likewise, responses to stress are broad and can include anger and hostility, emotional suppression or repression, and disengagement, all of which are similarly confounded with other constructs. Further, the nature of stressors can be confounded with traumatic events depending on how the individual experiences the event.

There is compelling, albeit limited, research that has demonstrated a relationship between the experience of negative life events, especially those that are objectively measured and chronic in nature, and functional changes in the immune system. The possible association between stress and the development and progression of serious illnesses such as coronary heart disease and cancer will need to be studied more extensively before researchers have a better understanding of the potential interplay between them. Some effective interventions for stress have been developed, including stress management techniques, but these are closely related to relaxation treatment approaches designed to treat anxiety. It does appear that the treatment literature emphasizes a cognitive behavioral perspective that, given the role of appraisals and coping mechanisms, holds considerable promise.

### The Concept of Stress

The term *stress* is typically meant to describe an individual's response to negative life events and involves cognitive, behavioral, emotional, and physiological components. Due to its multifaceted nature, the concept of stress has proved to be an imprecise term for the purpose of scientific investigations. Stress has been operationalized in many ways, and as such, it is often confounded with depression, anxiety, lack of social support, Type A behavior, hostility, and anger. Although no consensus has been achieved regarding the definition of stress, one generally accepted conceptualization of stress is that it is a response to a threat or environmental challenge that exists on a continuum between excitement and anxiety and is normally experienced as

tension or negative affect. The severity of the individual's response depends on the degree to which he or she feels a sense of control over the challenge and the level of belief he or she has about the ability to cope effectively with the challenge. Stress has various dimensions, including its duration (acute vs. chronic), quantity (discrete events vs. cumulative events), and quality (interpersonal vs. noninterpersonal events).

Several factors contribute to a stress response. In order for a stress response to occur, there must be the presence of a stressor. Stressors are events or conditions that present a demand or challenge or in some way constrain the individual and may involve catastrophic events (e.g., a natural disaster or being the victim of violence or war), major life changes, minor events, or chronic conditions (e.g., occupational stress). Lazarus and Folkman also noted the importance of cognitive appraisal in the stress process. An event needs to be judged in two ways: One is its relevance to one's physical and psychological well-being, and the other is whether one has the resources available to cope with the problem. This appraisal process influences the quality and intensity of one's emotional response as well as guides the selection of either emotion-regulation or problem-solution strategies for coping.

### Physiology of Stress

There also appears to be consensus that stress involves a physiological response. While Selye initially popularized the concept of stress, the first researcher to describe the phenomenon was Cannon, who described the "fight or flight" response. Selye later observed a set of generalized physical processes that he termed the general adaptation syndrome (GAS), which is the body's response to the awareness of a harmful stimulus and the interpretation of that stimulus as threatening. Current conceptualizations underscore how stress is mediated through the nervous, endocrine, and immune systems. The autonomic nervous system, with its sympathetic and parasympathetic branches, serves a particularly important role in the fight or flight response. The interplay of these systems has implications for the effects of stress on health and illness. For example, the role of one of the cranial nerves, the vagus, is involved with sympathetic activity with regard to heart rate and heart rate variability (HRV). Reduced HRV has been implicated in cardiac disease as well as in both anxiety and depression. Similarly, a real or perceived threat involves the hypothalamic pituitary axis, which

activates a number of hormonal responses that have long-term implications for physical functioning.

### The Assessment of Stress

Due to its multifaceted nature, stress has been assessed in a variety of ways. Given that life change is commonly implicated in the onset of the stress response, it is not surprising that this has been one focus of stress assessment. Holmes and Rahe developed a scale that incorporates both positive and negative life events that are weighted based on the degree of stress involved. There are also measures that assess the impact of traumatic events as well as daily hassles. In addition to self-report measures, there are interview and observational measures, such as those developed to assess Type A personality. There is also a substantial body of research examining how personality may be a risk factor for illness, with emphases on constructs as broad as neuroticism, and including anger, attachment style, emotional suppression, resiliency, helplessness, shyness, and so on. Given the emphasis on biological systems, stress has also been assessed in the laboratory measuring such diverse characteristics as the heart rate and HRV, skin conductance, muscle tension, and catecholamine and neurohormone levels, among others.

### The Relationship Between Psychological Stress and Physical Illness

There is compelling empirical evidence supporting the connection between stressful life events and changes in the immune system. In a meta-analytic review of studies examining the influence of stress on immunity changes, researchers found a significant relationship between stress and both functional and enumerative immune measures. The results indicated that objective reports of stress were related to greater immune changes than subjective self-reports of stress were, interpersonal life events were related to greater changes in some immune outcomes compared to nonsocial life events, and long-term naturalistic stressors were associated with immunological changes. A second meta-analysis of over 300 investigations of the relationship between stress and changes in the immune system found that acute, time-limited stressors brought about adaptive immunological changes consistent with fight-or-flight responses, while chronic stressors were correlated with the suppression of cellular and humoral indices. Similar to the former

meta-analysis, this review indicated that subjective reports of stress were not significantly related to immunological changes.

Conflicting evidence exists regarding the impact of stress on the onset or progression of coronary heart disease and cancer. There appears to be some evidence that acute and chronic stress may have important effects on coronary heart disease. However, this relationship has been viewed with some skepticism given the lack of consensus about how stress should be defined and measured as well as the complex nature of coronary disease. Stress may contribute to the development of cancer through its effects on primary cellular function, such as DNA repair, and it also appears that an individual's level of adjustment to having cancer may affect the progression of the cancer. The mechanisms involved in the relationship between stress and specific diseases are highly complex and therefore require additional prospective community-based studies to define this relationship.

### Treating Stress

Despite 2 decades of research in the area of stress and coping, no gold standard interventions have been developed for managing stress. Research on coping behaviors indicates that the manner in which a person responds to stress is greatly influenced by longstanding characterological traits and therefore may be only somewhat amenable to psychological interventions. However, researchers have demonstrated that stress management interventions can bolster the immune system during treatment for HIV-positive patients and that stress management, coping skills training, and social support have been shown to affect progression of cancer. An emerging area of research is that of *positive psychology*, which focuses on catalyzing positive change in the face of overwhelming stress. There are a growing number of research studies that demonstrate that interventions consistent with positive psychology are able to promote positive mood in individuals suffering from chronic stress. For example, researchers were able to increase positive affect in AIDS caregivers with the use of problem-focused coping, positive reappraisal, and the reframing of ordinary life events with positive meaning.

## SUE, DERALD WING (1942– )

---

Derald Wing Sue is undoubtedly one of the most prominent figures in the area of multicultural counseling and research. Throughout his career he has challenged the ethnocentric monoculturalism of Western psychology. He pioneered the field of multicultural

counseling through his vision, courage, and tireless efforts. Among his contributions are conducting research on Asian Americans' mental health, creating courses on multicultural counseling, addressing President Clinton's Race Advisory Board, forming the Asian American Psychological Association, serving as the president of several professional organizations, organizing a national multicultural conference and summit, authoring seminal books, editing several journals, and developing the criteria for multicultural competencies. He has authored or coauthored over 80 journal articles and book chapters, 12 books, and 15 media productions. Sue is currently a professor at Teachers College of Columbia University, professor emeritus at California State University, and the president of A Psychological Corporation, a consultation firm. He continues to conduct research and write in the area of racism and racial microaggression.

### Early Years

Sue was born in Portland, Oregon, the second oldest of five brothers and one sister. His father, who emigrated from China around the age of 13, and his Chinese American mother never received formal education beyond third grade. His father's pride in his cultural heritage and his mother's hard work in raising six children and working at various jobs shaped Sue's early years. Society's prejudice, discrimination, and racism toward him and his racial, ethnic identity also left their imprint on his early years. His family experienced financial hardships, and all the family members worked to contribute to the family budget. His parents emphasized the importance of a strong work ethic and the power of education, and all Sue children eventually received degrees from institutions of higher education. Sue's initial experiences with racism and discrimination came through institutions of formal education and the attitudes of childhood peers. His grade school teacher scolded him for speaking Chinese with his brother, the high school guidance counselor discouraged him from pursuing a career in social science because Asian Americans lacked social skills, and his peers teased him about the way he looked. These experiences eventually fueled his passion to understand the effects of racism and seek system-level change. Sue was also able to challenge his own attitude regarding his ethnic and racial identity, free himself from the limitations set by the society, and pursue a challenging yet successful career in psychology.

## Early Career Years

At a time when multicultural issues and racial equality were rarely, if at all, discussed, Sue was a true pioneer in bringing such issues to the attention of counseling psychologists. After obtaining his bachelor's degree from Oregon State University, and his master's and Ph.D. degrees from the University of Oregon, Sue worked as a counselor at the University of California at Berkeley's counseling center. He became known as the counselor who supported and helped Asian American students. During his years at Berkeley, he conducted studies on the mental health of Asian Americans. Inspired by his early work and research with Asian Americans, he coauthored the books *A Theory of Multicultural Counseling and Therapy* and *Understanding Abnormal Behavior*. Realizing his skill and joy in teaching, writing, and research, Sue transitioned into a tenure-track academic position at California State University at Hayward. He developed and taught the first multicultural counseling course and received the Outstanding Professor award in 1973.

## Major Contributions to the Field

During his undergraduate and graduate training, Sue was influenced by the teachings of the Black leaders of the civil rights movement, such as Martin Luther King and Malcolm X. During the years following his graduation, he witnessed the formation of Black, Latino, and Native American professional organizations. He was inspired to form the Asian American Psychological Association in collaboration with his brother Stanley Sue in 1972, and he served as the first president of the association. The following year, he was asked to serve as the guest editor for a special issue of the *Personnel and Guidance Journal*, and 3 years later he was appointed as the editor for this journal. During his editorship, he introduced changes to the format and content of the journal and emphasized cultural issues as well as prevention issues. He broadened the existing Black-White focus to encompass a more inclusive multiculturalism, addressing other ethnic groups. Although his vision for the journal was revolutionary in doing so, it met with considerable resistance from more senior members of the profession. He was reminded how difficult it can be to go against the status quo and bring about much needed change.

Despite the struggle of bringing changes to the field of counseling psychology, Sue continued to

make major contributions to the field. In 1997 he was invited to address President Clinton's Race Advisory Board. He discussed issues regarding racial equality and invited his countrymen and women to look at personal and institutional sources of racism. The same year he was also elected president of Division 45 (Society for the Psychological Study of Ethnic Minority Issues) of the American Psychological Association (APA). During his presidency he collaborated with other presidents to organize a national multicultural conference and summit in 1999. This conference and summit, now held every other year, facilitates a dialogue on issues of race, privilege, culture, and diversity among diverse groups of people and is now sponsored by professional organizations due to Sue's efforts to secure external funding.

Sue's book *Counseling the Culturally Diverse: Theory and Practice* was another major contribution to the field of counseling psychology. His book was one of the first textbooks that organized and integrated information on cross-cultural counseling and is considered a seminal book in graduate counseling training. In fact, it is used in approximately 50% of all counseling psychology training programs. His more recent publication, *Overcoming Our Racism: The Journey to Liberation*, was geared toward the general public in order to challenge individuals to acknowledge their racism and consider ways of moving toward societal equality.

Sue also theorized and defined multicultural competencies for more than 20 years. He chaired the committee instrumental in developing a list of multicultural competencies for counseling psychologists in 1980. Despite his continued efforts in this area for years, the criteria for multicultural competencies were not put in practice until 22 years later. In 2002 the APA adopted policies regarding guidelines on multicultural education, training, research, and practice.

## Recent Work

In 2007 Sue's recent work has focused on racial microaggressions and the Asian American experience. He believes that overt expression of racism has evolved into more subtle, ambiguous, and unintentional manifestations toward Asian Americans in American social, political, and economic life. Racial microaggression describes racism that occurs daily in the lives of individuals who are ethnically different from the mainstream. People of color experience

subtle insults, comments, or put-downs that happen automatically and unconsciously.

Asian Americans are often perceived as the “model minority” and as successful and exempt from racism. This stereotype has often pitted Asian Americans against other people of color. Using qualitative methods, Sue gleaned various themes and created a taxonomy of microaggression. These themes provided support for the notion that microaggressions continue to affect the lives of Asian Americans. Once again, Sue continues to push multicultural research forward by delving deeper into the various aspects of subtle and implicit racism and the impact it has on people of color.

Sue has held various roles as an educator, researcher, scientist, and social justice advocate. These roles have been fostered by his other roles as son, brother, husband, and father. Sue’s work has continually challenged the current social status and incorporated other worldviews. Personal reflections on Sue by his colleagues and students often emphasize the effect that his science and his search for justice have had on the field of psychology. Sue continues to promote the goal of social justice, which incorporates full and equal participation of all groups in a society that is mutually shaped to meet the needs of all groups. The commitment to social justice includes a vision in which the distribution of resources is equitable and all members of society are physically and psychologically safe and secure. It is evident that Sue’s lifelong work has focused on this goal by informing and educating academicians, practitioners, and business about the importance of rights and privileges for all groups.

## SUICIDE POSTVENTION

---

Suicide postvention is a response or reaction to a community or individual following a suicide attempt or completion by someone known to that community in order to facilitate healthy psychological adjustment. Suicide postvention typically involves counselors or others in paraprofessional roles providing factual information about the attempt or completion, educating those affected by the suicide about the expected range of emotional and psychological responses, offering referrals for further psychological services, and providing opportunities for follow-up consultations.

Counselors participating in suicide postvention strive to ensure that those affected by the suicide are coping in a healthy manner that will lead to resuming normal functioning rather than developing chronic, severe psychological symptoms. For example, postvention programs educate survivors on how to distinguish between expected bereavement symptoms and prolonged, more severe symptoms of depression that are cause for concern. One indicator of healthy adjustment to a suicide comes when survivors are able to talk about both positive and negative attributes of the deceased. With suicide, in particular, it is also important for postvention to help survivors move on from the question of why an individual committed suicide, because fixating on this difficult question can keep survivors from progressing through the bereavement process.

Postvention programs also prepare communities to expect a wide range of emotional or cognitive reactions to a suicide, depending on the survivors’ proximity to the victim. For example, some survivors might feel anger toward the victim, while others who have experienced the long-term depression of or threat of

suicide from the victim might feel a sense of relief when finality is reached. Both of these reactions can be normalized during postvention.

Postvention programs also strive to ensure that others do not attempt or complete suicide in response to the original event. Well-meaning communities may highly publicize a suicide in a way that gives significant attention to the victim or portrays the individual in a heroic light. However, suicide postvention programs are focused on acknowledging the individual's or community's loss without glorifying suicide in a way that could entice others to attempt it in order to receive similar attention. As part of a postvention response, counselors may facilitate community discussions about how to best commemorate or honor the victim's life without glorifying the death.

Communities, such as schools, churches, or other organizations, are best served by comprehensive suicide postvention plans that are circulated among all potential responders before a suicide occurs. Such plans include information about what local psychological services are available to those affected by a suicide and identify who will serve as the overall postvention coordinator, media liaison, and community relations liaison.

Comprehensive suicide postvention programs also can include what some researchers have termed a "psychological autopsy." The psychological autopsy involves learning about the events leading up to the victim's suicidal behavior, possibly by reviewing medical records or interviewing friends or family who might have known about the victim's thoughts, feelings, problems, or behaviors.

Overall, postvention programs are valuable to communities because they can help return affected individuals and groups to presuicide levels of functioning relatively quickly while simultaneously preventing copycat suicides.

## SUPERVISION

---

The supervision of counselor and psychotherapist supervisees is one of the most important processes in training individuals to become practicing counseling psychologists. Supervision is the process by which a more experienced professional provides oversight, guidance, and consultation to one or more less experienced professionals (junior colleagues) or to one or more trainees aspiring to enter the profession (students). The primary function of this relationship, which extends over time (usually months, sometimes years), is to ensure that quality services are provided by the supervisee. A secondary, but very important, function is to enhance the professional development of the trainee. These goals are accomplished through the development of a facilitative relationship between the supervisor and supervisee that includes components of evaluation, teaching and learning, counseling and support, and consultation.

### The Supervision Process

#### **Supervisor Role**

Supervisors are typically associated with the same agency or training program as their supervisees. They are responsible for ensuring that quality services are provided by the supervisees to their clients and that these services are delivered in a manner consistent with ethical guidelines of the profession (e.g., those of the American Psychological Association or the American Counseling Association) and relevant law. In addition, supervisors are also typically responsible for providing

administrative oversight for the supervisee, making sure that procedures, paperwork, and so on required by the agency are followed. To accomplish this, supervisors must have ongoing access to all relevant information concerning the supervisee's work with clients, including client files, case notes, and assessment information as well as the ability to monitor the supervisee's interactions with clients through direct observation, video, or (minimally) audio recording mechanisms.

Supervisors typically meet weekly for at least an hour with each of their supervisees and may have additional meetings with groups of supervisees that allow trainees to learn from and give input to colleagues. It is also often necessary, depending upon the level of experience of the supervisee and the presence or absence of other qualified personnel at the agency, for the supervisor to be available at times when the supervisee is working with clients for immediate consultation or crisis intervention. Early on in the supervisory relationship, the availability of the supervisor and regular supervision sessions need to be arranged. In addition, mechanisms should be arranged for feedback to the supervisee from the supervisor and to the supervisor from the supervisee. The specific domains of professional practice that the supervisee will engage in and the method for evaluating the effectiveness of service delivery by the supervisee should be clarified and agreed upon. It is important that the supervisor is competent in the domains of professional practice that will be supervised in addition to having competence in the supervisory process itself.

Supervisors are also responsible for encouraging the professional development of their supervisees. Thus, supervisors need to be aware of the level of competence of their supervisees for the various professional activities they will engage in under supervision. Generally speaking, the less experience and competence the trainee has in particular activities, the more structure, specific direction, and information are provided by the supervisor. Supervisors should also be familiar with various modes of supervision (e.g., individual, group, direct observation, case conferences) as well as different classes of supervisory interventions (e.g., support, positive reinforcement, prescriptive directives, problem solving, process comments).

### **Supervisee Role**

Supervisees may engage in a breadth of professional activities depending upon the training setting.

They may do individual, marital and family, or group counseling or psychotherapy as well as assessments, consultation, supervision of others, psychoeducational programs, and so on. Supervisees typically have had some prior instruction regarding the particular domains of activity they will engage in while being supervised, so that they have a foundation of knowledge from which to develop intervention skills. Additional information and perspectives as well as skills in case conceptualization and implementing interventions are acquired by the supervisee through the supervisory process.

For supervisees to experience optimal development through supervision, as well as to ensure client welfare, they must approach the supervision process with an openness and willingness to learn. To receive the most useful input from their supervisors, supervisees must be willing to share all relevant aspects of their interactions with clients as well as their reactions to them. They must be willing to be observed and be open to feedback and direction from their supervisors. It is also crucially important for supervisees to familiarize themselves with ethical guidelines that guide professional practice and to commit themselves to adherence to these guidelines. Finally, client welfare and the intent to provide effective services must be viewed as paramount by supervisees.

### **Growth of the Field**

Some form of supervision and training has probably occurred since early practitioners began engaging in counseling and psychotherapy. Unfortunately, it took considerable time for the process to be subjected to empirical scrutiny and for specific models to be developed to explain and guide the practice. For example, Carl Rogers, the pioneer of client-centered therapy, noted in 1957 that research in supervision was rare but that platitudes were plentiful. A fairly common assumption at the time was that if one could do counseling and psychotherapy, then one could supervise others doing counseling and psychotherapy. This perspective continues today, although it has been challenged by the emergence of specific models of supervision training and development.

An early and continuing perspective on supervision has viewed the process as an extension of theories of counseling and psychotherapy. For example, in 1972, R. Eckstein and R. Wallerstein published a volume on supervision and described the process as

going through stages in which early assessments of strengths and weaknesses of both supervisor and supervisee lead to attributions of authority as well as influence. Confrontations and conflicts that surfaced along with defenses and avoidance were worked through, which eventually led to more independence of the supervisee.

The 1960s and 1970s saw a dramatic growth of the influence of client-centered therapy, which translated into facilitative approaches to supervision. Although modeling served as an important component of training, R. Carkhuff and B. Berenson found that aspects of client-centered therapy such as support, empathy, warmth, and genuineness by the supervisor were characteristic of effective supervision. Similarly, behavioral therapists (and, later, cognitive-behaviorists) viewed supervision as assisting the supervisee in directing the behavior of his or her clients toward specified goals. Learning how to use aversive conditioning, goal setting, counter conditioning, systematic desensitization, and later, cognitive restructuring and other treatments is the primary focus of supervision. Proficiency is developed through an apprenticeship with an experienced therapist in which the supervisee becomes more knowledgeable about learning theory. Similarly, practitioners who use systemic and family systems theories have devised approaches to supervision using interventions that are consistent with those used by systemic therapists with their clients (e.g., strategic or paradoxical interventions).

Another important category of supervision models includes those that rely less on adherence to a particular theory and more on the process and the specific tasks of supervision. An example of this approach is the skills training model, which is widely used in early methods and techniques of counseling courses. A. Ivey has been influential in proposing that a communication skills laboratory approach is an effective method of training. In this approach, specific skills are learned in limited and focused training segments. These skills are assumed to be fundamental across most, if not all, approaches to counseling and psychotherapy. A variation of this approach by N. Kagan includes the client in a process review of what occurred during a counseling session and the client's reactions to the process. An important contribution of the skills training approach, in addition to delineating "core" counseling skills, is the amount of research stimulated by the models. Although some studies indicated that the approach was superior to the facilitative model of supervision, others suggested that the skills

learned through this approach didn't transfer well to other situations and would decay over time. However, the skills training model remains a broadly used approach for training beginning counselors and psychotherapists.

Another example of an atheoretical approach to supervision is J. Bernard's discrimination model. This approach limits its focus to process skills (interventions), conceptualization skills, and personalization skills. Consistent with earlier models, the supervisor is viewed as assuming certain roles in assisting supervisees; these include the teacher role, the counselor role, and the consultant role. Other atheoretical models examine the context of supervision as it occurs within multiple interacting systems, including those represented by the client, supervisee, supervisor, and the agencies in which they function. Additional models have conceptualized supervision from an eclectic or integrative approach, relying on various theories of psychotherapy to generate interventions and approaches to the supervision process.

Most models of supervision have little direct empirical support to argue for their efficacy. Although these models and their descendents remain influential in the practice of supervision, the field has moved toward models that conceptualize the supervision process as different from counseling and therapy and largely independent of the type of therapy that is being supervised. For example, B. Kell and J. Burrow offered a blended model of supervision that relied on psychodynamic theory, a facilitative style of therapy, and used behavioral terminology. The supervisor engaged in the role of therapist when helping the supervisee deal with anxiety and conflict, in the role of teacher in tracing the sources of conflict, and as a consultant to advanced trainees who set their own goals for supervision. Additional work by J. Fleming in 1953 and R. Hogan in 1964 formed the basis for conceptualizing the supervision process from a developmental perspective, which remains an important influence in models of training and supervision research today.

As a prelude to the growth of developmental models of supervision that occurred in the 1980s and 1990s, J. Littrell, N. Lee-Borden, and J. Lorenz examined common roles of supervisors at the time and integrated them into a single model. The supervisor roles of teacher, counselor, consultant, and self-supervisor were combined into a sequence that suggested a developmental influence. Two later models were instrumental in integrating developmental theory into an approach to supervision. The first supervision model

that attempted to integrate developmental theory into the supervision process was proposed in 1981 by C. Stoltenberg, who built upon Hogan's early ideas and introduced concepts from theories of cognitive development. This model viewed trainees as moving through four stages: (1) anxious and dependent, (2) less anxious with a dependency-autonomy conflict, (3) conditional dependency, and (4) culmination, in which the trainee had become a fully functioning autonomous professional. Specific supervision environments were proposed that started with high levels of structure provided by the supervisor and moved toward more supervisee structured and collegial supervision as the supervisee gained experience.

The next year, C. Loganbill, E. Hardy, and U. Delworth published a supervision model that also relied heavily on developmental theory. This approach also conceptualized the supervision process as a stage model that describes trainee growth over time through three stages while eight content issues (e.g., competence, emotional awareness) provide the basis for examining and assessing this growth. This model views trainees as recycling through this developmental process to ever deepening levels.

In the late 1980s, Stoltenberg and Delworth collaborated in publishing the integrated developmental model of supervision (IDM), which built upon two earlier models and more fully integrated developmental issues with the growing body of research on supervision. Among other issues, the revised model attends more directly to domains of professional activity and posits that trainees develop in similar ways but often at different rates across these domains. Thus, supervisors must be cognizant of the differing developmental levels of their supervisees for various domains (e.g., intervention skills competence, psychological assessment, consultation). Development is monitored (and encouraged) across these levels and domains by attending to a progression of change in supervisees for the structures of awareness, motivation, and autonomy. As supervisee professional development occurs within these domains, the supervisor also attends to integrating this growth across domains. The model was expanded and updated again in the late 1990s (with B. McNeill) and remains influential today.

Research addressing developmental models of supervision has been extensive and has been viewed as largely supportive of the important constructs of the models, although problems with the quality of the studies have been raised. In addition, developmental models have been faulted for being too complex as

well as too simplistic to fully explain the supervision process.

Constructs from developmental theories have also been applied to supervisors, positing similar processes in the growth of competence in conducting supervision as is seen in counselor and psychotherapist development. More specifically, the development of internship directors, interns, and postdoctoral fellows has also been examined.

## Current Status

In general, supervision appears to be an effective mechanism for training professional psychologists. As the number of scholarly articles and research studies examining the supervision process has grown from a few studies prior to 1980 to an impressive body of work, supporting evidence has accumulated. Based on a range of studies, although some of them provide only indirect support, it appears that supervision and training enhances outcomes for the clients of the supervisees. It is also apparent that supervision increases proficiencies in supervisees. Research on psychotherapy has indicated that the therapist–client working alliance is important for success in therapy, and research in supervision suggests that the supervision process enhances the supervisory working alliance, which in turn has a positive impact on the therapist–client working alliance. In addition, evidence suggests that mere experience in conducting counseling and psychotherapy doesn't enhance therapist development as much as when these experiences are supervised. Thus, it appears that having the opportunity to process what occurs in therapy sessions with a more experienced supervisor enhances the professional development of the supervisee.

Although supervision has been assumed to be an important process in the education and training of counselors and psychotherapists for decades, it has achieved the status of a professional competency only over the last 10 or so years. Important guidelines by professional associations (e.g., the Association of Counselor Education and Supervision, the American Psychological Association Committee on Accreditation) have increased the attention paid to the competency and training of supervisors. However, recent surveys still find that many professional psychologists across settings provide supervision with little formal training in how to do it or exposure to models of supervision. Consequently, they have limited or no familiarity with the empirical research literature that examines the utility and limitations of the supervision process. Thus,

many supervisors still largely rely on their own personal experiences in supervision and their understanding of the practice of counseling and psychotherapy to guide their work with their supervisees.

This contrast between the professed importance of supervision to the training of counselors and psychotherapists and the lack of training in this area for most supervisors has prompted increased attention to indices of competence in the practice of supervision. For example, the Association of Psychology Postdoctoral and Internship Centers organized a conference in 2002 that was cosponsored by 34 professional associations and was attended by 127 delegates (mostly psychologists). The charge of the conference was to explore and articulate the competencies psychologists should acquire across a breadth of professional domains, including supervision. A working assumption of the work group examining supervision competence was that the process is developmental in nature. One of the products of this event was the delineation of a number of aspects of competencies for supervisors. Information, attitudes, skills, and values necessary for one to perform as an effective supervisor were addressed. Specifically, these included knowledge bases such as the area being supervised (clinical domain), models and modalities of supervision, and relevant research, ethics and legal issues, evaluation, and diversity.

Similarly, a set of skill areas for supervisors were offered as important for effective supervision, including building a working alliance in supervision, promoting trainee growth, assessment of self and trainee skill levels, teaching, using and delivering formative and summative feedback, setting boundaries, and scientific thinking. Values were also seen as important areas of competence, including assuming responsibility for supervisee training, reaching a balance between clinical and training needs, sensitivity to diversity, using scientific research, and knowing one's own limitations. It was also concluded that supervisors should receive formal training, including courses in supervision addressing the knowledge and skill areas of the field. Also, applied training was viewed as critically important, including receiving direct supervision by an experienced supervisor of the supervision provided to trainees. This supervision of supervision should include direct observation (live, video, or audio) of the supervision process by a competent supervisor. Suggestions were also made regarding how these competencies could be assessed.

In order for a supervisor to encourage the growth of supervisees, it is helpful to have articulated competencies for effective counselors and psychotherapists. To be most useful, these competencies should be organized into expectations for various levels of training of supervisees. R. Hatcher and K. Lassiter, in a report written for the Association of Directors of Psychology Training Clinics, conceptualize supervisees as changing in their response to training in counseling and psychotherapy in a progression from novice to intermediate, advanced, proficient, and expert levels. They delineated competencies as including personality characteristics, intellectual and personal skills, knowledge from classroom experience, relationship and interpersonal skills, and competencies in working with colleagues and supervisors, among others. The intent of the report was to describe core competencies for professional psychologists and characterize the level of competency to be expected at the end of the practicum experience prior to internship training.

Taking this report and other studies together, it is evident that the field of supervision has made considerable progress in articulating competencies required for professional psychologists and trainees. Reaching these competency goals is enabled by conducting effective supervision informed by knowledge of models of the supervision process, particularly those that articulate a developmental sequence to guide training for various levels of trainees. Finally, competencies that lead to augmenting the influence of the skilled supervisor and forming baseline expectations for the practice of supervision are becoming more clearly defined. A better, more complete picture is emerging of the characteristics of trainees at different points in the training process and of how to encourage their development through levels of professional competency. In addition, the competencies associated with effectively guiding the supervision process and evaluating this progress are becoming clearer. However, a great deal of work is needed to more adequately delineate and expand upon our understanding of the process of supervision as well as evaluate the effectiveness of the training process.

## Future Directions

It appears likely that the growth in attention to issues related to supervision will continue into the foreseeable future. The next 5 to 10 years are likely to bring about more specific guidelines for the practice of supervision

and the credentialing of psychologists who engage in it. Professional ethical guidelines call for psychologists to practice within their areas of competence. As supervision competencies become more clearly articulated, providing evidence for these skills, attitudes, and values will become more important. The American Counseling Association has supported the establishment of training standards for supervisors, and organizations within the field of psychology have shown similar interest in examining this possibility for the training of professional psychologists.

Although the growth of scholarship and research in supervision has been impressive over the past couple of decades, much work remains in investigating the supervision process. For example, it is not clear why at a given point in time for a particular trainee a specific supervisory intervention is effective, when at other times or when used with other trainees it may be ineffective. Attention to issues related to trainee characteristics and needs at different levels of development may shed much needed light on this issue, but specific evidence is lacking. Similarly, why certain interventions that appear to work for some trainees frustrate and inhibit the growth of others needs further clarification. Again, perhaps timing is an important consideration, as the structure and prescriptive interventions that a supervisor might use effectively with a trainee of limited experience may produce resistance and lack of progress with a more experienced supervisee. On the other hand, providing the limited structure and guidance favored by more experienced supervisees may elicit distracting anxiety and confusion in inexperienced supervisees. More specifically, for the same trainee, will these different approaches prove more or less effective depending upon the particular domain of practice that is the focus of supervision at any given point in time? Indeed, do supervisees develop at different rates across domains of practice as a function of experience and training? How do personal characteristics of the supervisee and supervisor (including racial/ethnic/cultural identity) affect the supervision process and, subsequently, the outcomes with clients?

The scientist-practitioner training model that is characteristic of the field of counseling psychology holds much promise for advances in our knowledge and practice of supervision. Through extensive research on supervision informed by practice, and through the practice of supervision informed by research, competence as a field in this important

training process should continue to be enhanced. Ultimately, this should have a positive impact on service delivery to clients.

## TECHNOLOGY AND TREATMENT

---

Technology provides tools to help counselors accomplish their work more effectively and efficiently beyond what they can do without it. Counselors now have high-tech methods for better managing, supporting, conducting, delivering, and describing their work as before never imagined. Such power, however, comes with great responsibility. Counselors must work diligently to make certain that technological literacy and implementation is an important part of their ongoing professional development. They must identify and plan for overcoming barriers that technology can pose, such as intrusions into personal lives. Finally, counselors must recognize how the very same technology that helps them can hurt themselves and their clients. Thus, important parts of counselors' technological literacy and implementation are understanding potentials and opportunities that technology affords counselors, evaluating how technology is used, and considering the impact that technology has on their lives.

Technology is having a profound impact on every aspect of life, including how people work, how they play, and even how they view the world. The introduction of technology into counseling is an evolutionary process that is happening quickly, if not always easily. Those who grew up at a time when there were no computers have struggled to gain the skills necessary to function in a rapidly changing, technologically literate society, while those of younger generations use technology almost effortlessly, because they were introduced to it at a very early age. The most recent advances in assessment and diagnosis, counseling

techniques, and career development utilize technology in one fashion or another. From Internet-based counseling to telecounseling, the range of human services provided in schools, agencies, and private practice is changing and advancing.

### **The Nature of Counselor Technological Literacy**

So what is technological literacy as it pertains to counselors? Many people have written on the subject of technological literacy. Technological literacy may be seen as having knowledge and abilities to select and apply appropriate technologies in a given context. There are three components to technological literacy: the technology of making things, the technology of organization, and, the technology of using information. Applying a Delphi technique to opinions expressed by experts, Croft evolved a panel of characteristics of a technologically literate student. Those are abilities to make decisions about technology; possession of basic literacy skills required to solve technology problems; ability to make wise decisions about uses of technology; ability to apply knowledge, tools, and skills for the benefit of society; and ability to describe the basic technology systems of society.

A theme among various attempts to define technological literacy is that technology has evolved to become a powerful medium—not only a set of high-tech tools. If technology functioned merely as a set of tools, the problem of advancing technological literacy would not be so challenging. But technology has become more than a set of devices to be picked up and used when a person decides he or she needs them.

It has become a required medium that mediates experience in most aspects of peoples' lives. Broadly speaking, technological literacy, then, can be described as the intellectual processes, abilities, and dispositions needed for individuals to understand the link between technology, themselves, and society in general. Technological literacy is concerned with developing one's awareness of how technology is related to the broader social system and how technological systems cannot be fully separated from the political, cultural, and economic frameworks that shape them.

This means that counselors who have adequate levels of technological literacy are able to understand the nature and role of technology in both their personal and professional lives; understand how technological systems are designed, used, and controlled; value the benefits and assess the risks associated with technology; respond rationally to ethical dilemmas caused by technology; assess the effectiveness of technological solutions; feel comfortable learning about and using systems and tools of technology in the home, in leisure activities, and in the workplace; and critically examine and question technological progress and innovation.

### How Counselors Use Technology in Their Work

Counselors use technology to help them be more effective and efficient in their work, ultimately maximizing positive counseling outcomes, in one or more of the following four areas:

1. *Information/Resource.* In the form of words, graphics, video, and even three-dimensional virtual environments, technology affords counselors a dynamic and rapidly growing library of information and knowledge.
2. *Communication/Collaboration.* Chat rooms, bulletin boards, virtual shared environments, video conferencing, online conferences, electronic meeting services, e-mail—technology now enables people to connect, exchange information, collaborate, and make shared decisions.
3. *Interaction/Productivity.* The maturing of software and Web-based programming has launched a new level of available tools, both off the shelf and customized for the counseling professional. These high-tech tools can help counselors build and create anything ranging from a personalized business card to a set of personalized Web site links. For

example, interactive tools help counselors to process data and manipulate information, convert text to speech, create a graph, or even determine the interactive effects of popular prescription drugs.

4. *Delivery of Services.* Most controversial, yet growing in popularity, is counselors' use of technology to meet with clients and deliver counseling services in an online or virtual environment (i.e., at a distance).

Across these four areas, counselors are incorporating technology in their work in many different ways. Following is a cross-section of examples:

A therapist recorded an in-session relaxation session as well as specific exchanges between the clinician and client focusing on specific client difficulties such as mastering a breathing technique. This custom-made tape then becomes a review for the client in the following days as he or she works on relaxation at home. The same therapist used recording technology with another client whom he instructed to tape "conversations with yourself" to better identify irrational, unrealistic, or illogical thinking patterns.

Susan, a community counselor, needed to provide periodic reports to a funding agency regarding the nature of clients served by her counseling group over several months as part of a grant. Counselors where she worked used a software program shared over a network for record keeping, so that demographic data, diagnostic information, treatment plans, and insurance information—among other types of information—were uniformly stored for each client. The system allowed Susan to choose data of interest and then add several basic formulas to aggregate the data to display descriptive statistics (e.g., average client age, percentages of clients with certain diagnoses, changes in GAF scores over time). Finally, she merged relevant information into a report template provided by the funding agency. After she generated the first report, subsequent reports required only that she repeat the procedure for exporting the data from the system and then copy and paste the existing formulas instead of recreating them.

One school counselor conducted a psychoeducation group for all students at the same time by creating a multimedia presentation, transferring it to video, and then broadcasting it on the school's television network. For classes that had computers, the counselor

used the Internet to conduct a live chat about the topic. For classes that did not have computers, the counselor followed up that day and conducted live discussions.

### **Online Counseling**

One area of technology that seems to be receiving the greatest amount of attention is online counseling. This type of counseling goes by names such as e-therapy, e-counseling, cybertherapy, and telecounseling. Specifically, online counseling refers to counseling that occurs across some distance instead of in an office setting with both counselor and client in the same room or office. According to Sabella, the continued evolution of the Internet offers many future possibilities and much potential for this type of counseling.

### **Delivery of Services**

Counseling over the Internet may be a useful medium for those with physical disabilities who find traveling even a short distance to be a significant obstacle. For others who are reticent to meet with a counselor or who have difficulty with self-disclosing, the Internet may foster the counseling process. Similarly, the Net is a convenient and quick way to deliver important information. In cybercounseling, information might be in the form of a homework assignment between sessions or bibliocounseling. Also, electronic file transfer of client records, including intake data, case notes, assessment reports, and selected key audio and video recordings of client sessions, could be used as preparation for individual supervision, group supervision, case conferences, and research.

### **Assessment and Evaluation**

Access to a wide variety of assessment, instructional, and information resources in formats appropriate in a wide variety of ethnic, gender, and age contexts could be accomplished via the World Wide Web.

### **Communications**

Especially via e-mail, counselors and clients can exchange messages throughout the counseling process. Messages may inform both counselor and client of pertinent changes or progress. E-mail can provide an excellent forum for answering simple questions, providing social support, or scheduling actual or virtual meeting times.

### **Marriage and Family Counseling**

If face-to-face interaction is not possible on a regular basis, marriage counseling might be delivered via video conferencing, in which each couple and the counselor (or counselors) are in different geographic locations. After independent use of multimedia-based computer-assisted instruction on communication skills, spouses could use video conferencing to complete assigned homework (e.g., communication exercises).

### **Supervision**

Anecdotal evidence has shown that e-mail is an enhancing tool in the process of counselor supervision and consultation. It provides an immediate and ongoing channel of communication between and among as many people as the counselor or supervisor chooses.

### **Credentials**

Because cybercounseling can occur anytime and anywhere, it may pressure the profession and governance to formulate a national, or perhaps international, counseling licensure or certification. Definitely an enormous undertaking, this measure would facilitate uniform standards of training and practice while expediting reciprocity among states and countries. Cybercounseling may very well become the impetus for the ultimate in counselor credential portability.

### **Potential Pitfalls**

#### **Confidentiality**

Although encryption and security methods have become highly sophisticated, unauthorized access to online communications remains a possibility without special attention to security measures. Counselors who practice online must ethically and legally protect their clients, their profession, and themselves by using all known and reasonable security measures.

#### **Computer Competency**

Both the counselor and client must be adequately computer literate for the computer/network environment to be a viable interactive medium. From typing skills to electronic data transfer, both the counselor and client must effectively harness the power and function of both hardware and software. As in face-to-face counseling, cybercounselors must not attempt to

perform services outside the limitations of their technological competence.

### ***Location-Specific Factors***

A lack of appreciation on the part of geographically remote counselors of location-specific conditions, events, and cultural issues that affect clients may limit counselor credibility or lead to inappropriate counseling interventions. For example, a geographically remote counselor may be unaware of recent traumatic events at the local level exacerbating a client's reaction to work and family stressors. It may also be possible that differences in local or regional cultural norms between the client's community and the counselor's could lead a counselor to misinterpret the thoughts, feelings, or behavior of the client. Counselors need to prepare for counseling a client in a remote location by becoming familiar with the client's recent local events and local cultural norms. If a counselor encounters an unanticipated reaction on the part of the client, the counselor needs to proceed slowly, clarifying clients' perceptions of their own thoughts, feelings, and behavior.

### ***Equity***

Web counseling has the potential to exacerbate equity issues already confronting live counseling. If counseling online is a viable alternative, steps need to be taken to ensure that costs do not create another obstacle for some clients. As well, if some service providers view cybercounseling as an inexpensive alternative, then it may inappropriately become the tool for those who cannot afford more traditional approaches. Alternatively, if cost issues are addressed and access is available equally for everyone, cybercounseling may further alienate potential clients who have less technological expertise, creating a different type of equity gap.

### ***High Tech Versus High Touch***

How can counselors foster the development of trusting, caring, and genuine working relationships in cyberspace? Until virtual reality is realized for individuals and small institutions, cybercounseling relies on a process limited in nonverbal or extraverbal behavior. Questions remain about whether counseling can be effectively conducted without an actual human

presence—a presence that includes a holistic experience greater than the sum of its parts.

### ***Impersonation***

Many people hide behind the Net's veil of anonymity to communicate messages they ordinarily would not communicate in real life. The reality is that it is almost impossible to know who a cyberclient really is. A client who is a minor may depict himself or herself as an adult. Other clients may disguise their gender, race, or other personal distinctions in a manner that threatens the validity or integrity of the counselor's efforts.

### ***Credentials***

One of the counseling profession's main concerns will be those who are unlicensed persons promoting themselves as competent Internet counselors. When a counselor is unlicensed, a state has no regulatory authority, unless there is a law in that state that will allow prosecution for practicing counseling without a license as a criminal act or that gives the state's licensing board regulatory authority. According to Hughes, unlicensed cybercounselors are legally almost untouchable, especially when they display a disclaimer stating that what they are doing is not therapy.

More than ever before, cybercounseling may have created a need for the profession to educate consumers about choosing an appropriately trained and credential counselor. Many questions regarding cybercounseling and credentials need to be answered: How will insurance companies handle requests from cybercounselors interested in purchasing professional liability insurance specifically to conduct cybercounseling? How will certification and licensure laws apply to the Internet as state and national borders are crossed electronically? Will cybercounselors be forced to maintain licensure or certification in the states in which their clients reside, or must counselors only obtain licensure or certification in the state from which they practice? Similarly, who will monitor service complaints out-of-state or internationally?

### ***Ethics***

How do current ethical statements for counselors apply or adapt to situations encountered online? For

the most part, counselors can make the leap into cyberspace and use current ethical guidelines to conduct themselves in an ethical fashion. However, problems exist. The future will inevitably see a change in what it means to be ethical as we learn the exact nature of counseling online.

## TEENAGE PARENTS

---

Teenage parenthood is a social problem in Western culture. This is due, in part, to concerns about the ability of adolescents to meet their own needs for identity exploration and development while also meeting the developmental needs of an infant for stability and commitment. Further, teenage parenthood presents a long-term economic stress to society, as teenage mothers are often unmarried, rarely able to support themselves, and at risk for dropping out of high school, thereby reducing future employment options. The inability of teenage parents to financially support themselves results in a significant burden to the

welfare system. Yet, despite numerous programs designed to prevent teenage pregnancy, the United States remains the industrial nation with the highest rate of teenage births.

The availability of birth control, legal abortion, and adoption suggests that adolescent parenting is not wholly due to ignorance or accident. Although teenagers may not fully comprehend the implications and expectations of parenthood, there are, at least for some, positive aspects of becoming a parent within their social context. In order to understand the reasons that teenagers become parents and their special needs as parents, this entry addresses the psychosocial factors that influence teenage pregnancy and parenthood and the risk and protective factors associated with their outcomes.

### Becoming a Teenage Parent

Historically, teenage pregnancies have been viewed as accidental, a function of limited resources, early sexual activity, and poor access to family planning. However, the number of young women and men who continue to become teenage parents, including those who have multiple children within a period of a few years, suggests that other factors contribute to this phenomenon.

Many studies have identified risk factors for becoming a teenage parent with the goal of using this information to prevent teenage pregnancy and parenting. Relative to older first-time parents, adolescent parents are more likely to live in poverty and have unsuccessful educational experiences, while a disproportionate number evidence psychiatric concerns or a history of abuse. They are also more likely to have had teenage parents, and to become sexually active at a younger age, than are older first time parents. Many of these factors are interrelated. For example, adolescents who experience early abuse are more likely to experience psychiatric disorders, while youth who have experienced abuse or psychiatric problems are more likely to engage in early sexual behavior.

While the risk factors for adolescent pregnancy are clear, there is less understanding of why adolescents, after becoming pregnant, decide to parent their children. In some instances, adolescent women may have limited knowledge of their alternatives. Other explanations also help account for the continued expansion of this group, however. Some teenage women who become parents perceive themselves as

having limited options in the workforce as a function of having unsatisfying educational experiences and as a result of living in communities with high rates of unemployment and poor job satisfaction. Motherhood provides a role definition for these teens. In instances where teenage parents had teenage parents, they may be modeling their parents' early sexual activity and lifestyle. Studies in which teenage mothers have been interviewed find them identifying positive aspects to early parenting, including strong feelings of connection to their families and the fathers of the children and positive attention from others. Even when support from the family of origin and the father of the baby are not forthcoming, adolescent girls may embrace motherhood because of feelings of connection toward their children. From a societal viewpoint, this accelerated role transition to parenthood is problematic because of concerns about the mother's ability to adequately parent her child, and the need for external resources to sustain the mother and child. However, these young mothers already experience high levels of stress and may find additional fulfillment in their role as parents.

There are significant racial differences in the prevalence of teenage parenting. Both African Americans and Latino ethnic groups have a higher proportion of teenage mothers than do Caucasians. This is largely accounted for by the disproportionate number of African Americans and Latinos with risk factors for teenage pregnancy, including low income and limited educational success. There are a disproportionate number of multigenerational, ethnic minority families with teenage parents, making early sexual activity and parenting the norm for some communities, which contributes to the perpetuation of this cycle.

### **Outcomes for Teenage Parents**

One of the major issues addressed in the literature is the extent to which teenage parents experience greater stress and have more long-term, psychosocial problems than do others. These findings depend on who the "others" are to whom teen parents are compared. In comparison to older first-time mothers, adolescent mothers report more psychological distress, including higher levels of depression, substance abuse, and domestic violence as well as more problems in parenting. However, teenagers who become parents differ from older first-time parents on a number of psychosocial dimensions prior to becoming parents.

Teenage parents are more likely to be poor, be less educated, come from less stable homes, and themselves have younger parents than do those who first parent as adults. Thus, differences in the distress exhibited by teenage parents and older parents in part reflect socioeconomic and demographic differences that existed prior to parenthood.

Because youth who become pregnant tend to come from poor socioeconomic environments, having a child may only minimally increase their already high level of stress while also providing them with an adult purpose in a social context in which they see limited options for themselves. Studies that compare adolescent parents to adolescents who are not parents but who come from similar socioeconomic backgrounds find fewer differences between these groups in terms of overall stress, although both groups tend to have high stress levels and a disproportionate percentage experience stress-related psychopathology. This suggests that the emotional distress found among teenage parents is largely, but not fully, due to the socioeconomic circumstances under which they live rather than their parenting responsibilities alone.

The demands of parenthood may interfere with normative adolescent development, including the development of a strong sense of self and an understanding of one's needs regarding a partner, schooling, and employment. Studies on the later psychosocial functioning of adolescent parents as well as the development of their children have yielded mixed results. Studies on small numbers of adolescents report positive or negative outcomes depending on the sample chosen. Larger studies tend to find a mix of outcomes, with some youthful parents successfully transitioning into adulthood and others continuing to have problems over a period of years.

One of the older longitudinal studies that included teen parents was conducted by Emmy Warner and Ruth Smith. They followed the entire birth cohort in Kauai in 1955, including 28 infants born to teenage mothers, for the next 30 years. While differing in ethnicity from adolescents in studies on the mainland, these teenage mothers shared many characteristics with those of other studies; most were from single parent homes, one third had been born to adolescent mothers, and a majority had problems in school as well as parents who also had limited education. However, over the course of time these young women became more self-sufficient. They obtained additional education when schooling was available at accessible

times, and they gained employment as their children entered school.

Given the heterogeneity in outcomes, understanding the risk and protective factors for teenage parent outcomes is critical for effectively serving this population. Key among these factors is support from one's family of origin and the mother's relationship with the father of the child.

### ***Family of Origin Support***

A key protective factor for teenage mothers is the presence of social support. Family support is particularly important for teenage mothers who are unmarried and may not have stable relationships with the fathers of their children. Teenage parents need continued support from their families to develop self-confidence and self-sufficiency as adults. They also need immediate instrumental support, including housing, financial assistance, child care, instruction on parenting, and help in completing their education and obtaining employment.

Support from extended family can be a strong protective factor for both the adolescent parent and the child. In many instances, both maternal and paternal grandparents play significant caretaking roles in the lives of their grandchildren. In some instances they provide the primary parenting to their grandchildren while continuing also to parent their adolescents. Support from extended family can provide respite for adolescent parents, allowing them to complete school and meet other developmental needs, while also modeling parenting behavior, teaching the adolescent to become more self-sufficient. Extended family members can influence child development directly and indirectly through their impact on the teenage mother and father.

However, the complex nature of new family relationships can also create stress. Criticism of the adolescent parent can interfere with his or her ability to learn to take responsibility for the child. Further, grandparents may experience stress in caring for an infant while also helping their adolescent gain necessary parenting skills. There are many instances in which this transition does not occur, and the grandparent remains the infant's primary caregiver. This pattern has been associated with increased rates of subsequent pregnancies for mothers in their teens. It is necessary to understand the family system of the adolescent in order to help the adolescent develop a plan that works for all.

### ***Teenage Fathers***

Research on adolescent parents has focused primarily on adolescent mothers. Thus, research on partner support focuses on adolescent fathers. Most adolescent mothers report an unmarried relationship with the father of the child before they became pregnant. The fathers of children born to adolescent mothers tend to be 2 to 4 years older than the mothers. Although there is a similar pattern of age difference between adult parents, some consider this age difference among adolescents as suggestive of an exploitative sexual relationship between older adult males and younger adolescent females.

Paternal involvement is often reported as a positive factor associated with lower maternal stress and better child outcomes. However, some fathers are abusive and increase the family stress rather than reduce it. The quality of the teenagers' relationship prior to parenthood predicts the likelihood that adolescent parents will remain together. If the father plays a role in the prebirth decision to raise the child, he is likely to have a higher level of involvement in the child's life. While fathers often report the intention to remain involved in their children's lives, consistent contact tends to decrease as the children become older. There are many factors that affect continued involvement, including lack of employment and financial stress. Continued paternal involvement may also be complicated by disapproval from the adolescent mother's family of origin, particularly if the teens are relying on them for housing and other financial support.

Although partner support is associated with positive psychosocial outcomes for the mother and child, teens who cite pregnancy as a primary reason for marriage evidence higher rates of divorce. Further, when there are different fathers for the adolescent mother's subsequent children, there is greater complexity of paternal involvement with each child.

### **Development of Children of Teenage Parents**

Children born to adolescent mothers are at risk for lower academic achievement, higher rates of emotional and behavioral problems, and poorer social adaptation than are children born to older mothers. However, most of these differences can be accounted for by the social and economic risk factors associated with teenage parenting; once poor socioeconomic

status, low maternal educational achievement, and single marital status are taken into account, the relationship between maternal age and adverse child outcomes is not significant. Maternal education is one of the stronger predictors of adverse outcomes for children; this is encouraging for those engaged in prevention and intervention efforts, in that education is a variable that can be targeted and changed.

While children born to adolescent parents are at greater risk than children born to older parents, many function within normal limits. Positive child outcomes are associated with the absence of multiple risk factors, such as maternal stress and abuse, and the presence of protective factors. Protective factors include characteristics of the child, such as intellectual ability and self-esteem; characteristics of the mother, such as low levels of depression; and parenting behavior, such as consistent and nonpunitive disciplinary practices. The presence of the father is a protective factor when he provides support to the teenage mother, thereby reducing her stress, but can also be a risk factor if he is abusive and increases the level of family stress.

### Interventions to Help Teenage Parents

Public interventions for teenage parents typically target those on public assistance, with the goal of making these parents more self-sufficient and less dependent on welfare. Typically, these programs provide case managers to help the adolescents obtain needed schooling, work training, and child care. Many of these programs have been successful in helping some teen parents remain in school, obtain a GED or high school diploma, and obtain employment. However, outcomes are often limited by the low educational achievement of some of the participants and by the other stressors that affect their performance.

Interventions have also been developed to encourage teenage parents to delay subsequent pregnancies. Studies find that a majority of teenage parents have a second child within 2 years of having their first child and that larger families create additional risks for child outcomes. These programs have had, at best, small impact on adolescent parents' family planning.

Finally, welfare policies frequently change with the intent of creating greater self-sufficiency among those on welfare by providing assistance to obtain schooling and employment. The impact of programs designed to

decrease reliance of teenage parents on welfare is unclear, and it warrants continued evaluation.

Although interventions designed to assist adolescent mothers with their education and employment have met with some success, interventions designed to reduce teenage pregnancy and parenting have not. Interventions to reduce teenage parenting may be more effective if they focus, instead, on changing the broader context in which teenage parenting occurs by creating educational and community environments that foster access to a wider range of options during these adolescents' formative years.

## TRANSLATION AND ADAPTATION OF PSYCHOLOGICAL TESTS

---

The translation and adaptation of psychological tests used for practice and research requires careful attention to issues of bias and equivalence. Thorough translation methods help reduce bias and enhance

equivalence of multilingual versions of a test. Of equal importance is statistical verification of equivalence.

*Equivalence* addresses the question of comparability of observations and test scores across cultures. Lonner described four types: functional, conceptual, metric, and linguistic equivalence. These refer to issues of comparability of behavior and concepts across cultures to issues of test item characteristics (form, meaning structure). Van de Vijver also discussed four types of equivalence. Construct *nonequivalence* refers to constructs being so dissimilar across cultures they cannot be compared. Construct equivalence occurs when a scale measures the same underlying construct and nomological network across cultural groups, but may not be defined the same way. With measurement unit equivalence, the measurement scales for the instruments are equivalent (e.g., interval level), but their origins are different across groups. Equivalence at this level may limit comparability of two language versions of an instrument. The origins of the two versions may *appear* the same (both include interval scales), but because of differential familiarity with the response format used (e.g., Likert scale), the two versions are not identical. The same holds if the two cultural groups vary in response style (e.g., acquiescence). At the highest level of equivalence is scalar equivalence or full score comparability. Equivalent instruments at this level measure a concept with the same interval/ratio scale across cultures and the origins of the scales are similar. At this level, bias has been ruled out and direct cross-cultural comparisons of scores on an instrument can be made.

*Bias* negatively influences equivalence and refers to factors limiting comparability of test scores across cultural groups. Construct bias occurs when a construct is not identical across cultural groups (e.g., incomplete construct coverage). Method bias may limit scalar equivalence and can stem from specific characteristics of the instrument (e.g., differential response styles) or from its administration. Item bias can result from poor translation and item formulation and because item content may not be equally relevant across cultural groups.

Use of proper translation procedures can minimize bias and help establish equivalence. The International Test Commission (ITC) published translation guidelines to encourage attention to the cross-cultural validity of translated or adapted instruments. The context guidelines emphasize minimizing construct, method, and item bias, and assessing construct similarity or

equivalence across cultural groups before embarking on instrument translation. The development guidelines refer to the translation process itself, while the administration guidelines suggest ways to minimize method bias. The interpretation guidelines recommend verification of equivalence between language versions of an instrument.

Two general approaches have been identified when translating or adapting tests. In the applied approach, items are literally translated. Item content is not changed to a new cultural context, and the linguistic and psychological appropriateness of the items are assumed. With the adaptation approach, some items may be literally translated while others require modification of wording and content to enhance their appropriateness to a new culture. This approach is chosen if there is concern with construct bias. For both approaches, attention to equivalence and absence of bias is important. Building on the ITC guidelines and the work of others, the following should be considered when translating or adapting tests.
